Table 2.02.16 (continued): Discrete Indigenous communities reporting sewerage system leakages and overflows[(a)(b)], by type of sewerage system, 2006

(a) In the 12 months before the survey.

(b) All discrete Indigenous communities for which data on sewerage system leakages and overflows were collected. All discrete Indigenous communities with a reported usual population of 50 persons or more, and communities which have a reported usual population of less than 50 persons but which are not administered by a larger discrete Indigenous community or Resource Agency.

(c) Includes whether experienced sewerage system leakage not stated.

(d) Includes type of sewerage system not stated.

(e) Components may not add to total as more than one response may be specified.

Healthy Living Practices

Connection to services does not necessarily mean that the housing facilities (for example, toilets, baths, showers, washing machines, cooking facilities and refrigerators) are functional. The 2008 NATSISS collected information on the functionality of key household facilities required to support Healthy Living Practices. This included the functionality of facilities required to support the following four Healthy Living Practices—washing people; washing clothes and bedding; removing waste safely; and improving nutrition: the ability to store, prepare and cook food. These data were self-reported by people in the households.

- In 2008, approximately 99% of Indigenous households reported that they had working facilities for washing people, 94% reported working facilities for washing clothes/bedding, 94% reported working facilities for storing/preparing food and 98% reported working sewerage systems (Table 2.02.20).
- The Northern Territory had the highest proportion of Indigenous households that reported that they did not have working facilities for washing people (4.1%), washing clothes/bedding (12%), storing/preparing food (17%) or working sewerage facilities (3.9%) (Table 2.02.20).
- The proportion of Indigenous households that reported that they did not have working facilities for washing people, washing clothes/bedding, storing/preparing food and working sewerage facilities was higher in remote areas (3.0%, 11%, 15% and 2.5% respectively) than in non-remote areas (1.2%, 5.0%, 4.4% and 1.4% respectively) (Table 2.02.21).
- Indigenous households in the most disadvantaged areas based on SEIFA index were more likely to not have working facilities for washing people, washing clothes/bedding, storing/preparing food and working sewerage facilities than those in the least disadvantaged areas (Table 2.02.22).
- A higher proportion of Indigenous households with three or more dependent children aged 0–4 years reported that they did not have working facilities for washing clothes/bedding or for storing/preparing food (12% and 14% respectively) than Indigenous households with no dependent children (5.7% and 5.5% respectively). The proportion of Indigenous households without working facilities for washing people and working sewerage facilities was similar for households with none, 1, 2 and 3 or more dependent children aged 0–4 years (Table 2.02.23).
- Access to functional facilities to support the first four Healthy Living Practices was greater in households that were not overcrowded and did not have structural problems (Table 2.02.24).
- Access to functional facilities to support the first four Healthy Living Practices was lower for those households that usually did not consume vegetables or fruit each day compared with households that consumed at least one serve of fruit or vegetables each day (Table 2.02.25).
- In 2008, 50,439 Indigenous households had major structural problems. The proportion of households that had major structural problems was greater in remote (34%), than non-remote areas (25%) (Table 2.02.26).

Data quality issues

Community Housing and Infrastructure Needs Survey (CHINS)

The 2006 CHINS collected information on a variety of topics from discrete Aboriginal and Torres Strait Islander communities throughout Australia and on Indigenous organisations that provide rental housing to Indigenous people. In 2006, CHINS information was collected on 496 Indigenous organisations, which managed a total of 21,854 permanent dwellings. The majority of those dwellings were located in the Northern Territory (6,448), Queensland (6,230), New South Wales (4,176) and Western Australia (3,462) (ABS 2007).

The CHINS survey covers only discrete Indigenous communities. In 2006, the CHINS collected information from 1,187 discrete Indigenous communities. This included approximately 92,960 Aboriginal and Torres Strait Islanders or 18% of the total Indigenous population. CHINS data is collected every 5 years. The data are collected from key personnel in Indigenous communities and housing organisations that are knowledgeable about housing and infrastructure issues.

The estimates are not subject to sampling error because the CHINS was designed as a complete enumeration of discrete Indigenous communities. However, data could not be obtained from a small number of communities. In addition, the community population was often estimated by community representatives without reference to records. Therefore, the data is subject non-sampling error.

Further information on the CHINS can be found in the publication *Housing and infrastructure in Aboriginal and Torres Strait Islander communities, Australia 2006* (ABS 2007).

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings, such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities, were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared with other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: User's guide, 2008* (ABS 2010).

Census of Population and Housing

The Census uses the National health data dictionary standard Indigenous status question and it is asked for each household member. Measures that are drawn from Census data are subject to broad data concerns relating to the unexplained growth in the Aboriginal and Torres Strait Islander population since the 1991 Census, and the limitations of self-identification. Other Census data issues relate to the accuracy of the Census count itself, for example, whether people are counted more than once, or are under-counted (ABS 1996).

For the 2002 NATSISS, it was estimated that there were 165,700 Indigenous households compared with 144,700 enumerated in the 2001 Census. Although the Census data are adjusted for under-counts at the person level to arrive at the estimated resident population, no such adjustment is done at the household level. This affects the accuracy of the person counts at the household level to provide adjusted household estimates.

List of tables

2.03 Environmental tobacco smoke

The number and proportion of Aboriginal and Torres Strait Islander children aged 0–14 years who live in households with regular smokers and number and proportion of households with Indigenous children aged 0–17 years in which there were regular smokers

Data sources

Data for this indicator come from the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) and the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS).

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of areas of social concern including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

Data analyses

Children living in households with smokers

- In 2007–08, there were around 122,000 Indigenous children aged 0–14 years living in households with a daily smoker. This represented 65% of all Indigenous children aged 0–14 years. In comparison, 32% of non-Indigenous children aged 0–14 years lived in households with a daily smoker (Table 2.03.1).
- In 2007–08, there were around 57,000 households with Indigenous children aged 0–14 years in which there were daily smokers. This represented 64% of all households with Indigenous children (Table 2.03.1).
- Approximately 22% of Indigenous children aged 0–14 years were living in households with a daily smoker who smoked at home indoors compared with 6.6% of non-Indigenous children of the same age (Table 2.03.1).

Table 2.03.1: Whether children aged 0–14 years are living in households with current daily smoker(s), by Indigenous status of children, 2007–08

Children living in households with smokers by state/territory

- In 2008, the proportion of Indigenous children aged 0–14 years who lived in households with daily smokers ranged from 53% in the Australian Capital Territory to 77% in the Northern Territory (Table 2.03.2).
- The proportion of Indigenous children aged 0–14 years who lived in households with a daily smoker who smoked at home indoors ranged from 13% in the Australian Capital Territory to 29% in Tasmania (Table 2.03.2).
- The proportion of households with Indigenous children aged 0–17 years in which there were daily smokers who smoked at home indoors ranged from 15% in the Australian Capital Territory to 29% in Tasmania (Table 2.03.3).

- In Queensland, Indigenous children were 2.5 times as likely as non-Indigenous children to live in households with a daily smoker who smoked at home indoors. In New South Wales and the Australian Capital Territory, Indigenous children were three times as likely, in Victoria, South Australia and Tasmania, four times as likely and in Western Australia five times as likely as non-Indigenous children to live in households with a daily smoker who smoked at home indoors (Table 2.03.2).

Children living in households with smokers by remoteness

- In 2008, a higher proportion of Indigenous children aged 0–14 years in *Very remote* areas lived in households with a daily smoker (77%) and in households with a daily smoker who smoked at home indoors (24%) than Indigenous children in *Major cities* and *Inner regional* areas (Table 2.03.4). The same pattern was evident for Indigenous households with Indigenous children aged 0–17 years (Table 2.03.5).
- In *Major cities,* Indigenous children were four times as likely to live in households with a daily smoker who smoked at home indoors as non-Indigenous children. In *Outer regional* areas, Indigenous children were three times as likely, in *Inner regional* areas, two times as likely, and in *Remote* areas, eight times as likely as non-Indigenous children, to live in households with a daily smoker who smoked at home indoors (Table 2.03.4).

Children living in households with smokers by selected population characteristics

- The proportion of Indigenous children aged 0–17 years who lived in households with a daily smoker was highest among households in the most disadvantaged SEIFA quintile and lowest among households in the least disadvantaged households (53% compared to 10%) (Table 2.03.6).
- The proportion of Indigenous children aged 0–17 years who lived in households with a daily smoker who smoked at home indoors was higher among households that were renters (79%) than households that were owners (19%) (Table 2.03.6).

Data quality concerns

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors

Care has been taken to ensure that the results of this survey are as accurate as possible. All interviews were conducted by trained ABS officers. However, some factor may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010).

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Imperfect recall or individual interpretation of survey questions may nevertheless affect some responses.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in Major cities, Inner and Outer regional areas and Remote and Very remote areas, but Very remote areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In Remote and very remote communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

Data for this measure come from the National Assessment Program—Literacy and Numeracy (NAPLAN) tests and the National Aboriginal and Torres Strait Islander Social Survey (NATSISS).

National Assessment Program – Literacy and Numeracy (NAPLAN)

The first National Assessment Program—Literacy and Numeracy (NAPLAN) tests were conducted in May 2008 for all Years 3, 5, 7 and 9 students in government and non-government schools. For the first time, all students in the same year level were assessed on the same test items in the domains of Reading, Writing, Language Conventions (Spelling, Grammar and Punctuation) and Numeracy. Prior to 2008, students had undertaken different tests in each state and territory. NAPLAN results have been reported annually since 2008 using five national achievement scales, one for each of the assessed aspects of literacy—Reading, Writing, Spelling, Grammar and Punctuation— and one for Numeracy. These reporting scales are constructed so that any given scaled score represents the same level of achievement over time (MCEECDYA 2008). In 2011, for the first time, the Writing assessment was based on a persuasive task. In previous years students were assessed using a narrative task. The change in the Writing genre was implemented to ensure a broader range of what is required in the curriculum is assessed (ACARA 2011).

Student achievements for literacy and numeracy are reported on five national achievement scales. The scales consist of 10 bands to cover the full range of student achievement across Year 3 to Year 9.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues concern including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Data analyses

Reading, writing and numeracy benchmarks

The proportion of Indigenous and non-Indigenous students who achieved the reading, writing and numeracy benchmarks in 2011 are presented in Tables 2.04.1, 2.04.3 and 2.04.9. Achievements in spelling and grammar and punctuation are also presented in Tables 2.04.5 and 2.04.7.

Reading

- Nationally in 2011, approximately 76% of Indigenous students achieved the Year 3 reading benchmark compared with 95% of non-Indigenous students; 66% of Indigenous students achieved the Year 5 reading benchmark compared with 93% of non-Indigenous students; 77% of Indigenous students achieved the Year 7 reading benchmark compared with 96% of non-Indigenous students; and 72% of Indigenous students achieved the Year 9 reading benchmark compared with 94% of non-Indigenous students (Table 2.04.1).

Writing

- Nationally in 2011, approximately 80% of Indigenous students achieved the Year 3 writing benchmark compared with 96% of non-Indigenous students; 69% of Indigenous students achieved the Year 5 writing benchmark compared with 94% of non-Indigenous students; and 67% of Indigenous students achieved the Year 7 writing benchmark compared with 93% of non-Indigenous students; and 55% of Indigenous students achieved the Year 9 writing benchmark compared with 86% of non-Indigenous students (Table 2.04.3).

Numeracy

- Nationally in 2011, approximately 84% of Indigenous students achieved the Year 3 numeracy benchmark compared with 96% of non-Indigenous students; 75% of Indigenous students achieved the Year 5 numeracy benchmark compared with 96% of non-Indigenous students; 77% of Indigenous students achieved the Year 7 numeracy benchmark compared with 96% of non-Indigenous students; and 72% of Indigenous students achieved the Year 9 numeracy benchmark compared with 94% of non-Indigenous students (Table 2.04.9).

Reading, writing and numeracy benchmarks by state/territory

The proportion of Indigenous students and total students who achieved the reading, writing and numeracy benchmarks in 2011 are presented in Tables 2.04.1, 2.04.3 and 2.04.9 by state and territory. Achievements in spelling and grammar and punctuation are also presented in Tables 2.04.5 and 2.04.7.

Reading

- The proportion of Indigenous students who achieved the Year 3 benchmark ranged from 40% in the Northern Territory to 88% in Victoria (Table 2.04.1).
- The proportion of Indigenous students who achieved the Year 5 benchmark ranged from 29% in the Northern Territory to 86% in the Australian Capital Territory.
- The proportion of Indigenous students who achieved the Year 7 benchmark was lowest in the Northern Territory (43%) and highest in Victoria (88%).

- The proportion of Indigenous students who achieved the Year 9 benchmark was lowest in the Northern Territory (37%) and highest in the Australian Capital Territory (89%).

Writing

- The proportion of Indigenous students who achieved the Year 3 benchmark ranged from 42% in the Northern Territory to 91% in Victoria (Table 2.04.3).
- The proportion of Indigenous students who achieved the Year 5 benchmark was lowest in the Northern Territory (29%) and highest in the Australian Capital Territory (87%).
- The proportion of Indigenous students who achieved the Year 7 benchmark ranged from 26% in the Northern Territory to 74% in Victoria and Queensland.
- The proportion of Indigenous students who achieved the Year 9 benchmark was lowest in the Northern Territory (23%) and highest in Victoria (67%).

Reading, writing and numeracy benchmarks by remoteness

Reading, writing and numeracy benchmarks by remoteness area and Indigenous status are presented in Table 2.04.11.

- In 2011, the proportion of Indigenous students who achieved the Year 3, Year 5, Year 7 and Year 9 reading, writing, spelling, grammar and punctuation and numeracy benchmarks were highest in *Metropolitan* areas and lowest in *Very remote* areas of Australia.
- The proportion of Indigenous Year 3 students who achieved the reading, writing, spelling, grammar and punctuation and numeracy benchmarks was 84%, 88%, 81%, 81% and 89% respectively in *Metropolitan areas*, and 45%, 46%, 34%, 34% and 63% respectively in *Very remote* areas.
- The proportion of Indigenous Year 5 students who achieved the reading, writing, spelling, grammar and punctuation and numeracy benchmarks was 77%, 80%, 79%, 76% and 84% respectively in *Metropolitan* areas and 26%, 28%, 31%, 24% and 42% in *Very remote* areas.
- The proportion of Indigenous Year 7 students who achieved the reading, writing, spelling, grammar and punctuation and numeracy benchmarks was 85%, 77%, 82%, 77% and 85% respectively in *Metropolitan areas* and 43%, 28%, 38%, 24% and 42% in *Very remote* areas.
- The proportion of Indigenous Year 9 students who achieved the reading, writing, spelling, grammar and punctuation and numeracy benchmarks was 78%, 63%, 79%, 70% and 78% respectively in *Metropolitan areas* and 29%, 21%, 34%, 18% and 34% in *Very remote* areas.

NAPLAN 2008 to 2011

Data on students at or above the national minimum standards for reading, writing, spelling, grammar and punctuation, and numeracy in Years 3, 5, 7 and 9 are available from 2008 to 2011. These data are presented in Table 2.04.13. Data on the mean scale scores of these students are presented in Table 2.04.14.

Reading

- Between 2008 and 2011 there was an increase in the proportion of Indigenous students achieving the Years 3, 5, 7 and 9 national minimum standards for reading.
- Over the same period, there was a decrease in the difference between Indigenous and non-Indigenous students who met the Years 3, 5, 7 and 9 national minimum standards for reading.

Writing

- Between 2008 and 2011 there was a decrease in the proportion of Indigenous students achieving the Years 5, 7 and 9 national minimum standards for writing. However, there was an increase in Indigenous students achieving the Year 3 national minimum standard for writing.
- Over the same period, there was an increase in the difference between Indigenous and non-Indigenous students who met the years 5, 7 and 9 national minimum standards for writing.

Spelling

- Between 2008 and 2011 there was an increase in the proportion of Indigenous students achieving the Years 3, 7 and 9 national minimum standards for spelling. However, there was a decrease in Indigenous students achieving the year 5 national minimum standard for spelling.
- Over the same period, there was a decrease in the difference between Indigenous and non-Indigenous students who met the years 3, 7 and 9 national minimum standards for spelling.

Grammar and punctuation

- Between 2008 and 2011 there was an increase in the proportion of Indigenous students achieving the Years 3, 5, 7, and 9 national minimum standards for grammar and punctuation.
- Over the same period, there was a decrease in the difference between Indigenous and non-Indigenous students who met the Years 3, 5, 7 and 9 national minimum standards for grammar and punctuation.

Numeracy

- Between 2008 and 2009 there was an increase in the proportion of Indigenous students achieving the Years 3, and 5 national minimum standards for numeracy. However, there was a decrease in Indigenous students achieving the year 7 and 9 national minimum standards for numeracy.
- Over the same period, there was a decrease in the difference between Indigenous and non-Indigenous students who met the years 3, 5 and 9 national minimum standards for numeracy.

(a) Equating one test with another is a complex procedure and involves some degree of statistical error. For this reason, there may be minor fluctuations in the average NAPLAN test results from year to year when, in reality, the level of student achievement has remained essentially the same. It is only when there is a meaningful change in the results from one year to the next, or when there is a consistent trend over several years, that statements about improvement or decline in levels of achievement can be made confidently. Some caution is required when interpreting changes in the performance across years (ACARA 2011).

(b) Difference is 2011 proportion minus 2008 proportion.

(c) Difference is non-Indigenous proportion minus Indigenous proportion

(d) A new Persuasive Writing scale was introduced in 2011. The Persuasive Writing results for 2011 should not be directly compared to the Narrative Writing results from earlier years.

NATSISS

School attendance

- In 2008, 83% of Aboriginal and Torres Strait Islander children aged 2–14 years usually attended school (Table 2.04.15).
- Over the same time period, around 26% to 33% of Aboriginal and Torres Strait Islander children in years 3, 5, and 7 missed school in the previous week. The main reason for this (9% to 11%) was that the school was not open or not available (Table 2.04.16).

Table 2.04.15: School attendance by Aboriginal and Torres Strait Islander children aged 2–14 years, 2008

	Age in years

Informal learning activities

- In 2008, 94% (180,736) of main carers of Indigenous children spent time doing informal learning activities with the child during the previous week. The most common activities were reading from a book (49%) and watching TV, video, or DVD (31%) (Table 2.04.17).

Table 2.04.17: Number and proportion of Indigenous children[(a)] participating in selected informal learning activities and time spent with main carer (hours per week), 2008

Whether main carer spent time doing informal learning activities with child last week		
	Number	**Proportion (%)**
Activities were undertaken with child	180,736	93.6
No activities were undertaken with child	12,394	6.4
Total	**193,130**	**100.0**
Not stated	119	0.1
Average number of hours main carer spent doing informal learning activities with child last week		
	Number	**Proportion (%)**
Less than 1 hour per day	17,480	9.1
1 to less than 2 hours per day	77,582	40.4
2 to less than 5 hours per day	72,200	37.6
5 hours or more per day	12,580	6.5
No time spent doing activities with child in last week	12,394	6.4
Total	**192,236**	**100.0**
Not stated	1,013	0.5
Informal learning activities main carer did with child last week[(b)]		
	Number	**Proportion (%)**
Read from a book	95,081	49.2
Told child a story	85,102	16.4
Listened to child read	72,346	13.9
Assisted with homework or other educational activities	73,314	14.1
Spent time with child using computer	52,769	10.1
Watched TV, video or DVD	161,381	31.0
Assisted with drawing, writing or other creative activities	91,775	17.6
Played music, songs, dance or other musical activities	119,515	23.0
Played a game or did sport together indoors or outdoors	105,033	20.2
Took part in or attended playgroup	17,470	3.4
None of the above	12,394	2.4

(a) Children aged 0–14 years.

(b) Respondents can report more than one activity so the sum of components will be more than 100%.

Bullying and treated unfairly at school

- In 2008, between 13% and 21% of Indigenous children were reported to have been bullied or treated unfairly at school because they were Indigenous (Table 2.04.18). In 2008, between 79% and 87% of Indigenous children were reported to not be bullied or treated unfairly at school.
- Of those Indigenous children at school in 2008 who were both bullied and treated unfairly, 75% to 94% were bullied or treated unfairly at their current school. Between 78% and 96% of students in years 3, 5 and 7 did not change school because of bullying or unfair treatment, while no effect on school attendance was reported for 66% to 71% of Indigenous children in these years because of bullying or unfair treatment (Table 2.04.19).
- The 2008 NATSISS found that between 62% and 86% of Indigenous children were treated unfairly at the current school. A large proportion of children in these years 3, 5 and 7 (90%, 92% and 95% respectively) did not change school because of this treatment (Table 2.04.20).

Data quality issues

NAPLAN

Literacy and Numeracy data are available from the ACARA National Assessment Program — Literacy and Numeracy (NAPLAN). Individual schools send this data under a set of protocols to the Test Administration Authorities for the states and territories. Data are then compiled by ACER and provided to ACARA for reporting in The National Report Achievement in Reading, Writing, Language Conventions and Numeracy which is published in December of each year.

Students are classified in three ways: assessed, exempt, absent/withdrawn. Participation rates are calculated on the basis of all assessed and exempt students as a percentage of the total number of students reported by schools, which includes those absent and withdrawn. Exempt students are defined as follows: Students with a language background other than English, who arrived from overseas less than a year before the tests, and students with significant intellectual disabilities may be exempted from testing.

NAPLAN reports the percentage of students who achieved at or above the national minimum standard. The complex process by which student scores are arrived at and distributed across the national achievement bands (using the Rasch model, a recognised analysis model for educational measurement) are agreed by states, territories and the Commonwealth and endorsed by the then NAPLAN Expert Advisory Group. Due to the complexities of the methodology, it is not possible (with the data currently provided) to give a simple computation of the precise number of students at or above the national minimum standard, which is best reported in the bands designed for that purpose.

Student achievements for literacy and numeracy are reported on five national achievement scales. The scales consist of 10 bands to cover the full range of student achievement across Year 3 to Year 9.

Participation rates for Indigenous students are reported for each of the domains of Reading, Writing, Language Conventions (Spelling, Grammar and Punctuation) and Numeracy by year level and state and territory. Participation rates differ across each of these domains.

Achievement rates as reported by band levels are provided for both Indigenous and non-Indigenous students by domain, year level and state and territory.

In the majority of tables, percentages are expressed to one decimal place. In a small number of cases, percentages are rounded to the nearest whole number.

The percentages of students represented in all tables are rounded and may not sum to 100.

The same tests are used for all schools and all students.

Average age and years of schooling for all students are reported as at the time of testing and there are minor differences between states and territories due to different schooling systems. Information on parent occupation/parent education is collected by schools on student enrolment and information on Indigenous status is taken from student test book covers. Data are reported for Indigenous students for each domain, year level, and state and territory. Further data are provided by geolocation.

The non-response for Aboriginal and Torres Strait Islander status is approximately 3 per cent nationally. This information is captured from student test book covers where 3 per cent of students did not state their Indigenous status on the test bookcover.

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82%

of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: User's guide 2008* (ABS 2010).

List of tables

2.05 Education outcomes for young people

Years 10 and 12 retention rates and Year 12 attainment rates for Aboriginal and Torres Strait Islander people

Data sources

Data for this measure come from the Australian Bureau of Statistics (ABS) National Schools Statistics Collection (NSSC) and the National Aboriginal and Torres Strait Islander Social Survey (NATSISS).

National Schools Statistics Collections (NSSC)

The National Schools Statistics Collection (NSSC) is a collaborative arrangement between state, territory and Australian Government education departments. It is managed by the Ministerial Council on Education, Early Childhood Development and Youth Affairs (MCEECDYA) Performance Measurement and Reporting Taskforce (PMRT). Information is provided on the number and characteristics of schools, students and staff. These data are derived from the annual Schools Census enumerated each August by the responsible authorities.

Apparent retention rates

Apparent retention rates are the percentage of full-time students of a given cohort group who continue from the start of secondary schooling to a specified year level. The term 'apparent' is used because the retention rate does not account for students repeating a year of school or migrating in or out of the Australian school student population or between states/territories. All full-time students enrolled at a school, including 'VET (vocational education and training) in Schools' students, but excluding people completing Year 12 through a vocational education facility, are included in retention calculations.

Year 10 apparent retention rates: Year 10 students as a proportion of the corresponding cohort from the first year of secondary schooling (Year 7/8).

Year 12 apparent retention rates: Year 12 students as a proportion of the corresponding cohort from the first year of secondary schooling (Year 7/8) or as a proportion of the corresponding cohort from Year 10.

Year 12 attainment rate: The proportion of Year 11 students who went on to achieve a Year 12 certificate.

Care should be exercised in the interpretation of apparent retention rates, because the method of calculation does not take into account a range of factors. At the Australia level, these include students repeating a year of education, migration and other net changes to the school population. At lower levels of disaggregation, additional factors affecting the data, such as enrolment policies (which contribute to different age/grade structures between states and territories), inter-sector transfers and interstate movements of students, have not been taken into account. These and other factors affecting the interpretation of apparent retention rates are being looked at, where possible, in the ABS's review of apparent retention rates.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of areas of social concern including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Data analyses

Apparent retention rates

Table 2.05.1 presents the apparent retention rates of Indigenous and non-Indigenous students from Year 7/8 to Year 10, Year 11 and Year 12; the apparent retention rate from Year 10 to Year 12; and the apparent retention rate from Year 11 to 12.

- In 2011, there were approximately 12,426 Indigenous students in Year 10 (approximately 4.5% of all Year 10 students), 9,129 Indigenous students in Year 11 (approximately 3.5% of all students in Year 11) and 5,781 Indigenous students in Year 12 (approximately 2.6% of all students in Year 12).
- In 2011, the apparent retention rate of full-time Indigenous students from Year 7/8 to Year 10 was 98.7% compared with 100.3% for non-Indigenous students.
- In the same year the apparent retention rate of full-time Indigenous students from Year 7/8 to Year 11 was 73.3% compared with 93.7% for non-Indigenous students.
- The apparent retention rate of full-time Indigenous students from Year 7/8 to Year 12 was much lower—48.7% compared with 80.7% for non-Indigenous students.
- Similarly, the apparent retention rate of full-time Indigenous students from Year 10 to Year 12 was much lower—53.5% compared with 80.6% for non-Indigenous students.
- This trend was also seen in the apparent retention rate of full-time Indigenous students from Year 11 to Year 12— 67.5% compared with 86.7% for non-Indigenous students.

Apparent retention rates by sex

- The apparent retention rates for Indigenous females were slightly higher than those for Indigenous males from Year 7/8 to Year 10 (99.0% compared with 98.4%); Year 7/8 to Year 11 (75.2% compared with 71.4%), Year 7/8 to Year 12 (51.3% compared with 46.1%)

Year 10 to Year 12 (55.6% compared with 51.5%), and Year 11 to Year 12 (68.5% compared with 66.4%) (Table 2.05.1).

Apparent retention rates by state/territory

- In 2011, Tasmania, the Australian Capital Territory and New South Wales had the highest retention rates of Indigenous students from Year 7/8 to Year 10 (115%,107% and 106% respectively), whereas the Northern Territory had the lowest (83%).
- Retention rates of Indigenous students from Year 7/8 to Year 11 were highest in the Australian Capital Territory (96%) and lowest in the Northern Territory (55%).
- The Australian Capital Territory (76%) and South Australia (68%) had the highest retention rates of Indigenous students from Year 7/8 to Year 12 and the Northern territory (33%) and Western Australia (40%) had the lowest.
- Tasmania had the highest retention rate of Indigenous students from Year 11 to Year 12 (86%), whereas the Northern Territory had the lowest (51%).
- Rates for Tasmania and the Australian Capital Territory should be interpreted with caution, because the small size of these jurisdictions means that relatively small changes in student numbers can create large movements in retention rates. Some rates exceeded 100%, largely reflecting the movement of students from non-government to government schools in Years 11 and 12; and in the Australian Capital Territory, some New South Wales residents from surrounding areas enrolled in Australian Capital Territory schools during secondary school.

Table 2.05.1 (continued): Apparent retention rates, by Indigenous status, sex and state/territory, 2011(a)(b)(c)(d)

(a) Although most students are recorded, it is likely that some are not accurately identified as Indigenous. Therefore, these statistics are likely to underestimate the number of Aboriginal and Torres Strait Islander students. In addition, the standard Indigenous status question has not yet been implemented in some jurisdictions.

(b) The following factors have not been taken into account in these statistics: students repeating a year of education, migration and other net changes to the school population, enrolment policies (including year starting high school which contributes to different age/grade structures between states and territories), inter-sector transfer and interstate movements of students.

(c) In small jurisdictions, relatively small changes in student numbers can create apparently large movements in retention rates.

(d) The inclusion or exclusion of part-time students can also have a significant effect on apparent retention rates, especially in South Australia, Tasmania and the Northern Territory, which have relatively large proportions of part-time students

(e) Data for Western Australia have been affected by changes in scope and coverage over time.

(f) Some ACT rates exceed 100%, largely reflecting the movement of students from non-government to government schools in Years 11 and 12, and of NSW residents from surrounding areas enrolling in ACT schools.

(g) In 2009, changes to the processing of Northern Territory enrolment data will affect comparisons with previous years of all numbers drawing on student data for the Northern Territory.

(h) Retention rate = Year 10, 11 or 12 students as a proportion of the corresponding cohort from the first year of secondary schooling (Year 7/8).

(i) Retention rate = Year 12 students as a proportion of the corresponding cohort from Year 10.

(j) Retention rate = Year 12 students as a proportion of the corresponding cohort from Year 11.

Source: ABS 2012, AIHW time series analysis of published data.

Apparent retention rates over time

Table 2.05.2 presents apparent retention rates over the period 1998–2011.

- Between 1998 and 2011 there was a significant increase in apparent retention rates for Indigenous students from Year 7/8 to Year 10, Year 11 and Year 12. The fitted trend implies an average yearly increase in the rate of around 1.1% for Year 10 (equivalent to a 17% increase over the period), 1.6% for Year 11 (equivalent to a 41% increase over the period) and 1.2% for Year 12 (equivalent to a 48% increase over the period).
- Over the same period there was a significant increase in apparent retention rates for Indigenous students from Year 10 to Year 12. The fitted trend implies an average yearly increase in the rate of around 0.8%, which is equivalent to a 25% increase over the period. The change in apparent retention rates for Indigenous students from Year 11 to Year 12 was, however, not significant. The fitted trend implied an average yearly change of 0.1%, which is equivalent to 0% increase over the period.
- Between 1998 and 2011 there was also a significant increase in apparent retention rates for non-Indigenous students from Year 7/8 to Year 10, Year 11 and Year 12 of 3%, 0.5% and 8% respectively. These increases were not as great as for Indigenous students.
- Over the same period there was a significant increase in apparent retention rates for non-Indigenous students from Year 10 to Year 12 of 5% and no significant change in apparent retention rates for non-Indigenous students from Year 11 to Year 12.

Both the National Indigenous Reform Agreement and the National Education Agreement aim to halve the gap in Indigenous Year 12 or equivalent attainment by 2020. Since 2010, as part of the Compact with Young Australians, COAG has been implementing a National Youth Participation requirement that required all young people to be in full-time education, training or employment or a combination of education and employment until age 17. This might have affected apparent retention rates to Year 10 and Year 12 since 2010.

NATSISS data

Table 2.05.3 presents survey data on school attendance by Aboriginal and Torres Strait Islander children in Year 9 (note that data on school attendance for younger children in presented in indicator 2.04). Table 2.05.4 presents data on types of assistance that would help Aboriginal and Torres Strait Islander secondary school students. These data are from the 2008 NATSISS.

- Just over one-third (34%) of children in Year 9 or higher missed school in the week before the survey. The main reasons for missing school were 'school not available/open (12%)' followed by 'child illness or injury' (8%) (Table 2.05.3).
- The type of assistance most recommended to help Aboriginal and Torres Strait Islander secondary school students complete Year 12 was support from friends, family and school (11%) (Table 2.05.4). Encouragement from elders and council was reported as the second most recommended type of assistance to help Indigenous secondary school students complete year 12 in remote areas.

Data quality issues

National Schools Statistics Collection

Indigenous identification

Information on Indigenous status is obtained from school enrolment forms which are generally completed by the primary carer of the child. The NSSC includes people who did not state their Indigenous status in the category 'non-Indigenous'.

There is some variability in the reporting of Indigenous status, particularly in relation to not stated responses. This may result in some under reporting of Indigenous status, see Appendix 2: Collection of Indigenous Status of Students (ABS 2012). Increases in the number of Indigenous students due to improvements in the reporting of Indigenous status may lead to increases in apparent retention rates for Indigenous students independently of changes in actual retention.

Retention data

Care should be taken in the interpretation of apparent retention rates (ARRs) as the method of calculation does not take into account a range of factors such as repeating students, migration, inter-sector transfers and enrolment policies. For further details on the accuracy of the NSSC methodology and apparent retention rates, see the Explanatory Notes of Schools, Australia (ABS 2012).

The ARR is based on those who are undertaking study at the year 10 or year 12 level as at August in the reference year and they may not go on to complete year 10 or year 12.

The ARR measures change over a period of time. The numerator and denominator are sourced from different annual cycles of the NSSC, to follow the same age-cohort. Given the long analysis period, student transitions, such as migration or re-entry to the school system, have an effect on the accuracy of this calculation. In addition, the denominator is sourced from two different NSSC years due to different starting years for secondary school. For example, for the ARR from year 7/8 to year 10 in 2009, the denominator for New South Wales, Victoria, Tasmania and Australian Capital Territory is sourced from NSSC 2006 (year 7) and for Queensland, Western Australia, South Australia and Northern Territory is sourced from 2007 (year 8).

Relatively small changes in student numbers can create apparently large movements in retention rates, particularly in small jurisdictions. In addition, the rates in the smaller jurisdictions may be noticeably affected by changes in such factors as the proportion of ungraded and/or mature aged students from year to year.

Before sending data to the ABS, each State education department cleans the data and removes duplicate records so that students are only counted once. Due to the different enrolment systems, the ability to remove duplicates varies among jurisdictions and this may result in over-reporting of school students in some states. Decreases in the number of students due to improvements in the identification and removal of duplicate enrolments may lead to decreases in ARRs independently of changes in actual retention.

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years.

Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010).

List of tables

2.06 Educational participation and attainment of adults

Educational participation (persons undertaking formal education or training) and educational attainment (persons who have completed a particular level of school education or non-school qualification).

Data sources

Data for this measure come from the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS), the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS), the National Centre for Vocational Education Research and the Department of Education, Employment and Workplace Relations Higher Education Statistics Collection.

Data presented have not been age-standardised, because education has not been found to be strongly associated with age in analysis of surveys such as the NATSIHS.

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

National Vocational Education and Training (VET) Provider Collection

The National Centre for Vocational Education Research is Australia’s main provider of vocational education and training (VET) sector research and statistics. VET is a national system designed to give workers the skills for particular occupations and industries. The VET sector includes providers that receive public VET funding, such as technical and further education organisations, higher education institutions, other government providers (for example, agricultural colleges), community education providers, government-funded private registered training organisations, schools funded through government allocations for VET, and all other Commonwealth and state recurrent and specific-purpose funded VET, regardless of the location of the training organisation.

Non-identification rates for Indigenous students in these data are high. Care also needs to be taken when comparing data across jurisdictions for load pass rates, as average module durations vary across jurisdictions.

DEEWR Higher Education Statistics Collection

The Australian Government Department of Education, Employment and Workplace Relations (DEEWR) is the responsible agency for the Higher Education Statistics Collection, which includes information from higher education institutions such as universities and colleges of advanced education. This data collection contains statistics relating to students enrolled in higher education courses between 1 January and 31 December of each year in each Australian higher education provider.

Although universities design and produce their own enrolment forms, DEEWR has provided institutions with suggested wording for questions relating to Indigenous status (ABS 2003). Approximately 3% of students in this data collection have a 'not stated' Indigenous status. At the moment these are recorded as non-Indigenous, although plans are under way to record the 'not stated' responses separately.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

Data analyses

Self-reported survey data

The 2008 NATSISS collected information on the educational institution currently attended, the highest level of schooling that Indigenous people aged 15 years and over completed, and the highest level of non-school qualification. These data are presented in Tables 2.06.1 to 2.06.25.

Educational institution currently attended

- In 2008, approximately 19% of Indigenous people and 16% of non-Indigenous people aged 15 years and over were currently studying. Indigenous Australians were twice as likely to be studying at secondary school (8%) as non-Indigenous Australians (4%).

However, non-Indigenous Australians were twice as likely to be studying at university or in higher education as Indigenous Australians (6% compared with 3%) (Table 2.06.1).

Educational institution currently attended by age and sex

- In 2008, a higher proportion of Indigenous females aged 15 years and over were currently studying (20%) than Indigenous males (18%). Approximately 16% of both non-Indigenous males and non-Indigenous females of the same age were currently studying (Table 2.06.2).
- Approximately 2% of Indigenous males and 3% of Indigenous females were currently studying at university or another higher education institution compared with 6% of non-Indigenous males and females.

Educational institution currently attended by state/territory and remoteness

- In all states and territories except the Northern Territory, there was a higher proportion of Indigenous persons currently studying than non-Indigenous persons (Table 2.06.3).
- The Australian Capital Territory had the highest proportion of Indigenous persons aged 15 years and over currently studying (27%) and the Northern Territory had the lowest proportion (14%) (Table 2.06.3).
- The proportion of Indigenous people who were currently studying at secondary school ranged from 6% in the Northern Territory to 11% in Tasmania. The proportion of Indigenous people currently studying at TAFE colleges ranged from 3% in the Northern Territory to 10% in the Australian Capital Territory (although this estimate has a high relative standard error and should be used with caution).
- A higher proportion of Indigenous Australians in non-remote areas were currently studying at secondary school (9%) and TAFE colleges or equivalent (7%) than those in remote areas (6% and 5% respectively). The proportion studying at university or other higher education institutions was 3%in non-remote areas and 1% in remote areas (Table 2.06.4).

Highest level of school completed

- In 2008, Indigenous adults aged 18 years and over were twice as likely as non-Indigenous adults to report that their highest level of schooling completed was Year 9 or below (34% compared with 16%). Year 10 or 11 was the highest level of schooling that 43% of Indigenous adults and 33% of non-Indigenous adults completed, and Year 12 was the highest level that 23% of Indigenous adults completed compared with 51% of non-Indigenous adults (Table 2.06.5).

Highest level of school completed by age and sex

- Indigenous Australians aged 65 years and over were much more likely to report that their highest level of schooling completed was Year 9 or below (82%) than Indigenous Australians of younger ages (Table 2.06.5).
- Indigenous Australians aged 18–24, 25–34 and 35–44 years were around five times as likely to report Year 9 or below as their highest level of schooling as non-Indigenous adults of the same age groups.
- In 2008, males and females in the Indigenous population reported similar levels of school completed, as did males and females in the non-Indigenous population (Table 2.06.6).

Highest level of school completed by state/territory and remoteness

- The proportion of Indigenous adults aged 18 years and over reporting Year 12 as their highest level of school completed ranged from 16% in the Northern Territory to 44% in the Australian Capital Territory. The proportion of Indigenous students reporting Year 9 or below as their highest level of schooling ranged from 18% in the Australian Capital Territory to 44% in the Northern Territory (Table 2.06.7).
- A higher proportion of Indigenous Australians aged 18 years and over in non-remote areas reported Year 12 as their highest level of school completed than their counterparts in remote areas of Australia (25% compared with 16%) (Table 2.06.8).
- In *Major Cities*, *Inner Regional*, *Outer Regional* and *Remote* areas of Australia, Indigenous Australians were more likely than non-Indigenous Australians to report that their highest level of schooling completed was Year 9 or below. (Data are not available for non-Indigenous in *Very Remote* areas).

Time series analyses

- A higher proportion of Indigenous Australians aged 18 years and over reported that the highest year of school completed was Year 12 in 2008 (23%) than in 2002 (19%) and in 1994 (9%). A higher proportion of non-Indigenous Australians aged 18 years and over in 2008 also reported that Year 12 was their highest year of school completed (51%) than in 2002 (40%) (Table 2.06.9).

Highest year of school completed by selected population characteristics

- In 2008, among Indigenous Australians who completed year 12, 91% spoke English at home, 81% lived in non-remote areas and 75% were employed. Among those Indigenous Australians who completed to year 9 or below, 81% spoke English at home, 69% lived in non-remote areas and 35% were employed (Table 2.06.10).

Highest year of school completed by summary health and population characteristics

- In 2008, nearly half of all Indigenous Australians aged 18 years and over, who spoke a language other than English as their main language at home reported their highest level of school completed was Year 9 or below, compared with a third of Indigenous Australians who spoke English as their main language (Table 2.06.11).

- For Indigenous Australians aged 18 years and over in 2008, those in the 1st quintile (lowest income) of household income were more likely than those in the 5th quintile (highest income) to report their highest level of school completed as Year 9 or below (45% compared with 19%) (Table 2.06.11).

Non-school qualifications

- In 2008, approximately 40% of Indigenous Australians aged 25–64 years reported they had a non-school qualification compared with 61% of non-Indigenous Australians of the same age (Table 2.06.14).
- The same proportion of Indigenous and non-Indigenous people aged 25–64 years had completed a certificate course in 2008 (both 25%). A much higher proportion of non-Indigenous Australians had a bachelor degree or diploma as their highest level of non-school qualification (25% and 10% respectively) compared with Indigenous Australians (7% and 6% respectively).

Non-school qualifications by age and sex

- For Indigenous Australians the age group with the highest rate of non-school qualifications was 35–44 years (43%). For non-Indigenous Australians the highest rate was in the 25–34 year group (70%) (Table 2.06.12).
- In 2008, a similar proportion of Indigenous males and females aged 25–64 years had a non-school qualification (41% and 39% respectively). Indigenous males were more likely to have completed a certificate course (27%) and less likely to have completed a diploma (4%) or bachelor degree or above (6%) than Indigenous females (22%, 7% and 7% respectively) (Table 2.06.13).

Non-school qualifications by state/territory and remoteness

- The proportion of Indigenous Australians aged 25–64 years with a non-school qualification ranged from 27% in the Northern Territory to 63% in the Australian Capital Territory (Table 2.06.14). Approximately 21% of Indigenous Australians in the Australian Capital Territory had completed a bachelor degree or above, whereas in the other states and territories this proportion ranged between 5% and 11%.
- The proportion of Indigenous adults aged 20–24 years who reported attaining at least a year 12 or equivalent, or AQF Certificate II or above ranged from 24% in the Northern Territory to 58% in Victoria. Overall, the proportion of Indigenous adults aged 20–24 years who reported attaining at least a year 12 or equivalent, or AQF Certificate II or above was much lower than for non-Indigenous adults (45% and 85%, respectively) (Table 2.06.15).
- In 2008, a higher proportion of Indigenous Australians aged 25–64 years in non-remote areas reported having a non-school qualification (45%) than Indigenous Australians in remote areas (26%) (Table 2.06.16).

Non-school qualifications over time

Table 2.06.17 presents the proportion of Indigenous and non-Indigenous Australians with non-school qualifications in non-remote areas in 1994, 2002 and 2008.

- The proportion of Indigenous people aged 25–64 with non-school qualification increased from 24% in 1994 to 45% in 2008.
- The proportion of non-Indigenous people aged 25–64 with a non-school qualification also increased; from 58% in 2001 to 65% in 2008.

Non-school qualifications by summary health and population characteristics

Table 2.06.18 presents the proportion of Indigenous and non-Indigenous Australians with non-school qualifications by selected health and population characteristics.

- In 2004–05, Indigenous Australians aged 25–64 years without a non-school qualification were more likely to report fair/poor health status than Indigenous Australians with a non-school qualification (32% compared with 26%) (Table 2.06.18).

Table 2.06.17: Proportion of non-school qualifications, by Indigenous status, non-remote areas, persons aged 25–64 years, 1994, 2002, 2008

Highest year of school completed by whether woman has had children

- In 2008, Indigenous females aged 18 years and over who had not had children were twice as likely to report Year 12 as their highest level of school completed (40%) as Indigenous females who had children (20%). A much higher proportion of Indigenous females who had children reported Year 9 or below as their highest level of school completed (34%) than Indigenous females who had not had children (17%) (Table 2.06.19).
- During 2008, less than a quarter (23%) of primary carers of Indigenous children aged 0–14 years reported Year 12 as their highest level of school completed and almost one-third (29%) reported Year 9 or below as their highest level of school completed (Table 2.06.20).

Non-school qualifications by whether woman has had children, and child's main carer

- In 2004–05, Indigenous females aged 25–64 years who had not had children were more likely to have a non-school qualification than Indigenous females who had children (51% compared with 35%). Indigenous females who had not had children were around twice as likely to have completed a diploma or bachelor degree or above as Indigenous females who had children (Table 2.06.21).
- During 2008, 36% of primary carers of an Indigenous child aged 0–14 years did not have a non-school qualification (Table 2.06.22).

Table 2.06.21: Indigenous females aged 25–64 years, by non-school qualification and whether the woman has ever had children, 2004–05

Post-secondary attainment

The 1994 National Aboriginal and Torres Strait Islander Survey (NATSIS) and 2002 and 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) collected information on the post-secondary attainment of Indigenous people. Table 2.06.23 presents the proportion of Indigenous people aged 18 years and over who completed a post-secondary qualification of certificate III or above by state and territory for 1994, 2002 and 2008.

- The proportion of Indigenous people aged 18 years and over with a qualification of certificate III or higher decreased from 26% in 1994 to 16% in 2002, before increasing to 23% in 2008.

Table 2.06.23: Post-secondary attainment of certificate III or above, by Indigenous people aged 18 years and over, 1994, 2002 and 2008

	1994	2002	2008
NSW	28.0	18.2	24.3
Vic	50.0	24.2	35.9

Other study and study intentions

The 2008 NATSISS collected information on other study and study intentions of Indigenous people. Tables 2.06.24 and 2.06.25 present information on future study intentions. Table 2.06.26 presents the reasons for not pursuing another education qualification in the last 12 months. Finally, Table 2.06.27 presents information on adult education about Indigenous culture.

- In 2008, 43% of Indigenous males and 53% of Indigenous females intended to study in the next 12 months. This proportion was highest for the 15–24 year old age group (61% for males and 79% for females) (Table 2.06.24).
- The main reason for future educational intentions was to increase knowledge and skills, followed by improving qualifications and getting a better job (Table 2.06.25).
- In 2008, 27% of Indigenous Australians 15 years and over wanted to study for an educational qualification in the last 12 months but did not. The main reasons for this were: too expensive/ financial reasons, caring for family members, and personal or other family reasons (Table 2.06.26).
- Fifty-four per cent of Indigenous people stated that they were not taught about Indigenous culture at school or as part of further studies. Those who did receive education about Indigenous culture mainly received this at primary or secondary school. The Indigenous cultural education received was accurate. 55% of the time, and 58% of respondents said that they learnt about the clan, tribe or language group that they identify with (Table 2.06.27).

Vocational education and training (VET) data

Educational attainment

Data on educational attainment in the vocational education and training sector are available from the National Centre for Vocational Education Research's National VET Provider Collection. Data collected in 2010 are presented below.

- During the year 2010, there were 13,904 course completions in the VET sector by Indigenous Australians aged 15 years and over. This constitutes 3.8% of the Indigenous population aged 15 years and over. In comparison, approximately 2.1% of the population of other Australians aged 15 years and over completed a course in the VET sector in 2008 (Table 2.06.28).
- Over the same period, a similar proportion of Indigenous and other Australians aged 15 years and over had completed a certificate IV course, diploma or higher (0.7% each). A higher proportion of Indigenous Australians aged 15 years and over had completed a certificate III (1.1%) than other Australians (0.8%), or certificate I/II, (1.9% and 0.5% respectively).

Educational attainment by age and sex

- A higher proportion of Indigenous males and females aged 15 years and over had completed a course in the VET sector than other Australian males and females (3.9% and 3.7% compared with 1.9% and 2.2% respectively) (Table 2.06.28).

(a) Represents number of completions, students may complete more than one course.

(b) Other includes those whose Indigenous status is unknown.

(c) Includes statements of attainment.

(d) The number of qualifications completed in 2010 are based on preliminary data and will be revised upwards in the next collection.

Notes

1. Percentages are calculated using the Indigenous and non-Indigenous estimated resident population for 2010.
2. Does not include students with age of not stated.
3. Persons includes those students who did not state their sex.

Source: AIHW analysis of NCVER, National VET Provider Collection, 2010.

Educational attainment by state/territory and remoteness

- In 2010, the proportion of Indigenous Australians aged 15 years and over who completed a VET course ranged from 1.8% in Tasmania to 2.6% in New South Wales and Queensland (Table 2.06.29). The Australian Capital Territory had the highest proportion of Indigenous Australians who completed a certificate IV, diploma or higher (1.1%).
- The proportion of Indigenous and other students who completed a VET course in 2010 was similar in Tasmania and the Northern Territory, whereas in New South Wales, Victoria, Queensland, South Australia, Western Australia and the Australian Capital Territory, the proportion of Indigenous students who completed a course in the VET sector was higher than other Australians.
- The proportion of Indigenous Australians aged 15 years and over who completed a course in the VET sector in 2010 was highest in Outer Regional areas (1.8%) and lowest in Remote areas of Australia (0.9%). Higher proportions of Indigenous Australians living in Major Cities and Inner and Outer Regional areas had completed a certificate IV, diploma or higher than Indigenous Australians in Remote and Very Remote areas (Table 2.06.30).

Table 2.06.30 (continued): Educational attainment in the VET sector, by Indigenous status, sex and remoteness area, 2010

(a) Represents number of completions, students may complete more than one course.
(b) Other includes those whose Indigenous status is unknown.
(c) Due to the availability of Indigenous remoteness population estimates, percentages are calculated based on the 2006 census populations for both Indigenous and Other Australians.
(d) Includes statements of attainment.
(e) The numbers of qualifications completed in 2010 are based on preliminary data and will be revised upwards in the next collection.

Notes

1. Percentages are calculated using the 2006 Indigenous and non-Indigenous estimated resident populations by ASGC remoteness category.
2. Does not include students with age of not stated.
3. Persons includes those students who did not state their sex.

Source: AIHW analysis of NCVER, National VET Provider Collection, 2010.

Time series analyses

- Between 1996 and 2010, the proportion of Indigenous students who had completed a course in the VET sector increased from 0.6% to 3.8% (this was a statistically significant increase of 0.2% each year). Over the same period the proportion of other students who had completed a course in the VET sector increased from 0.7% to 2.1% (this was a statistically significant increase of 0.1% each year) (Figure 2.06.1, Table 2.06.31).

Annual change %[(c)]	. .	0.2*	. .	0.1*
Change over period[(d)]	. .	419.5*	. .	162.1*

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the 14 reporting periods.

(a) Represents number of completions, students may complete more than one course.

(b) Other includes those whose Indigenous status is unknown.

(c) Average period change determined using regression analysis.

(d) Per cent change between 1996 and 2010 based on the average annual change over the period.

Notes

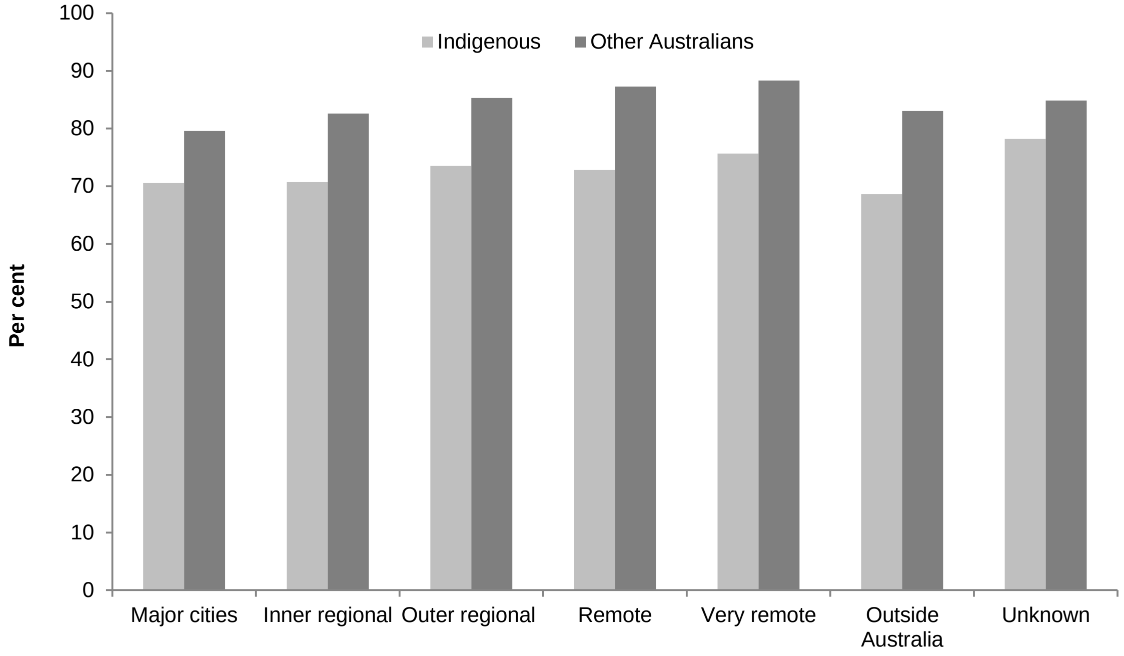
1. Other equal to domestic + International + not stated.
2. Does not include students with age of not stated.
3. The number of qualifications completed in 2010 are based on preliminary data and will be revised upwards in the next collection.
4. Data differs from numbers published in the 2010 Health Performance Framework due to revision and improvement in data qualifications and the inclusion of New South Wales data in 2008.

Source: AIHW analysis of National Centre for Vocational Education Research, National VET Provider Collection 2010, Figure 2.06.6, Table 2.06.43.

Load pass rate

The VET load pass rate indicates the extent to which students pass assessment in an assessable module or unit of competency. Load pass rates are calculated as the number of nominal hours supervised in assessable modules or units of competency completed with a pass assessment divided by the total nominal hours supervised in assessable modules or units of competency.

- In 2010, the VET load pass rate for Indigenous students was 72% compared with 81% for non-Indigenous students (Table 2.06.32). The rate was lower for Indigenous students than for non-Indigenous students across all geographical regions (Figure 2.06.2).



Source: NCVER, National VET Provider Collection, 2010.

Figure 2.06.2: VET load pass rate, by remoteness, 2010

Table 2.06.32: VET load pass rate[(a)], by remoteness, 2010

	Indigenous	Other Australians[(b)]	Ratio	Rate Difference[(c)]
Major cities	70.5	79.6	0.9	–9.0
Inner regional	70.7	82.6	0.9	–11.9
Outer regional	73.5	85.3	0.9	–11.8
Remote	72.8	87.3	0.8	–14.4
Very remote	75.7	88.3	0.9	–12.6
Outside Australia	68.6	83.1	0.8	–14.4
Unknown	78.2	84.8	0.9	–6.6
Total	**72.4**	**81.3**	**0.9**	**–8.9**

* Represents results with statistically significant differences in the Indigenous/Other Australian comparisons at the $p < 0.05$ level.

(a) Load pass rate= number of nominal hours supervised in assessable modules or units of competency with a pass assessment divided by total nominal hours supervised in assessable modules or units of competency.

(b) Other includes those whose Indigenous status is unknown.

(c) Rate difference is the Other Australian rate minus the Indigenous rate.

Source: AIHW analysis of NCVER, National VET Provider Collection, 2010.

Higher education data

Educational attainment

Data on the educational attainment of Indigenous Australians in the higher education sector are available from the Australian Government Department of Education, Employment and Workplace Relations. Data collected for the year 2010 are presented below.

- During the year 2010, approximately 0.4% of Indigenous Australians completed a course in the higher education sector compared with 1.3% of other Australians. Approximately 0.3% of Indigenous Australians completed an undergraduate degree and 0.1% completed a postgraduate degree. This compares with 0.6% for undergraduate and 0.7% postgraduate degrees for other Australians.

Educational attainment by age and sex

- Indigenous Australians aged 22–24 years were more likely to have completed a higher education course in 2010 (0.9%) than those in other age groups. Other Australians aged 22–24 years were also more likely to complete a higher education course in 2010 than those in other age groups (8.7%) (Table 2.06.33).
- In 2010, a higher proportion of Indigenous females than Indigenous males completed an undergraduate degree (0.4% compared with 0.2%) and a postgraduate degree (0.2% compared with 0.1%) (Table 2.06.33).

(continued)

Table 2.06.33 (continued): Completions in the higher education sector, by Indigenous status, sex and age group, 2010[(a)]

(a) Numbers are for all persons completing courses in higher education. Proportions have been calculated from persons aged 22 years and over, as this is the age group most applicable to higher education course completion.

(b) Other includes those whose Indigenous status is unknown.

(c) Includes postgrad. qual/prelim., grad.(post) dip.—new area, grad.(post) dip.—ext. area, and graduate certificate.

(d) Includes associate degree, advanced diploma (AQF), diploma (AQF) and other undergraduate award courses.

(e) Includes enabling courses and non-award courses.

(f) Includes undergraduate, postgraduate, domestic and international students.

Notes

1. Percentages are calculated using the Indigenous and non-Indigenous estimated resident populations for 2006.
2. Note that the numbers reported in the 2006 edition of this report under the higher education data section were for course enrolments rather than for completions as presented here.

Source: AIHW analysis of DEEWR Higher Education Statistics Collection.

- The proportion of Indigenous persons who completed a course in the higher education sector in 2010 ranged from 0.2% in the Northern Territory to 1.4% in the Australian Capital Territory (Table 2.06.34).
- A lower proportion of Indigenous persons completed a higher education course than other Australians in all states and territories.

Table 2.06.34 (continued): Completions in the higher education sector[(a)] by Indigenous status, sex and state/territory, 2010[(a)]

(a) Numbers are for all persons completing courses in higher education.

(b) Other includes those whose Indigenous status is unknown.

(c) Includes postgrad. qual/prelim., grad.(post) dip.—new area, grad.(post) dip.—ext. area, and graduate certificate.

(d) Includes associate degree, advanced diploma (AQF), diploma (AQF) and other undergraduate award courses.

(e) Includes enabling courses and non-award courses.

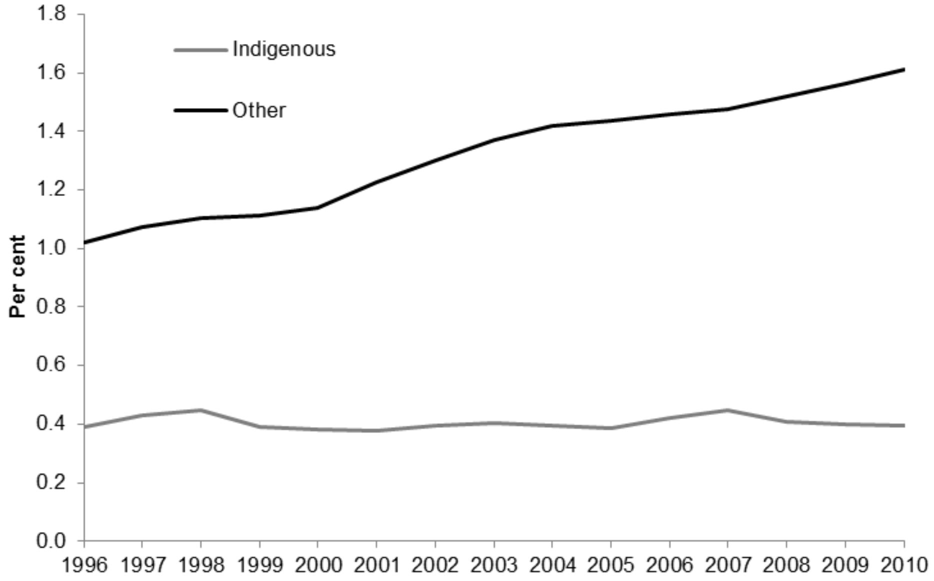
(f) Includes multi state completions.

Note: Percentages are calculated using the Indigenous and non-Indigenous estimated resident populations for ages 15 years and over in 2010.

Source: AIHW analysis of DEEWR Higher Education Statistics Collection.

Time series analyses

- Between 1996 and 2010, there was no significant change in the proportion of domestic Indigenous students who completed a higher education award course. During the same period of time, there has been a significant increase of 59% in the proportion of domestic other students who completed a higher education award course (Table 2.06.35, Figure 2.06.3).



Source: AIHW analysis of DEEWR Higher Education Statistics Collection.

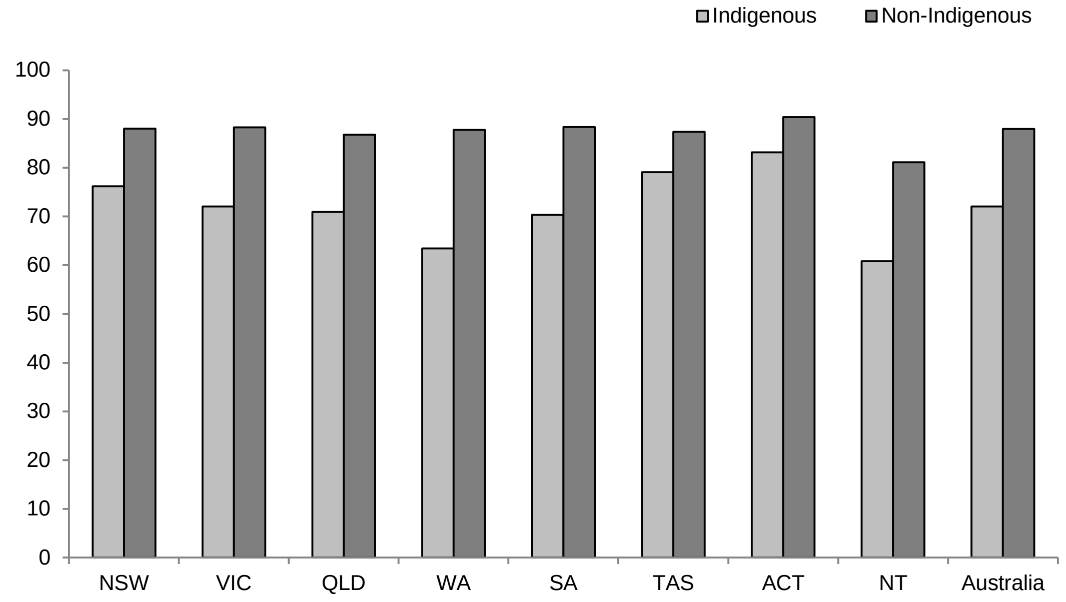
Note: Percentages are based on the 2006 residential estimates ages 15 and over.

Source: AIHW analysis of DEEWR Higher Education Statistics Collection.

Success rate

The success rate for higher education institutions is based on the proportion of units passed within a year compared with the total units enrolled.

- In 2010, the success rate for Indigenous students varied by state and territory, ranging from 61% in the Northern Territory to 83% in the Australian Capital Territory. The success rate for non-Indigenous students was similar in most states and territories (between 87% and 90%), except for the Northern Territory (81%) (Figure 2.06.4).
- The success rate was lower for Indigenous students than other students across all jurisdictions, with the largest difference in the Northern Territory (Table 2.06.36).



Source: AIHW analysis of DEEWR Higher Education Statistics Collection.

Additional information

Participation in Australian Apprenticeships

In 2006, the scheme formerly known as New Apprenticeships was re-named Australian Apprenticeships. The Australian Government provides incentives and personal benefits programs to encourage participation in this scheme. Involvement by Indigenous people in Australian Apprenticeships has been an ongoing success in the field of education and training.

According to DEEWR 2012, there has been continuous and strong growth in Indigenous participation in Australian Apprenticeships since 2001, and each year has been an improvement on the previous one.

- In 2008, there were 11,012 commencing Indigenous apprentices (3.8% of All Australian Apprenticeships commencements).
- In 2008, there were a total of 12,364 Indigenous apprentices-in-training (3.0% of All Australian Apprentices in-training).
- There has been an 86% increase in the overall number of Indigenous Commencing students since 2001 while as a proportion of all Commencing student apprentices, the Indigenous share has increased from 2.6% to 3.8%.
- The total number of Indigenous apprentices-in-training has almost doubled since 2001, increasing by 95%, while as a proportion of All apprentices-in-training, the Indigenous share has risen from 2.0% to 3.0%.

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010).

National Aboriginal and Torres Strait Islander Health Survey

The NATSIHS uses the standard Indigenous status question. The 2004–05 NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through

careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

National Centre for Vocational Education Research data

This collection gathers information from providers (in receipt of public VET funding) about activity of the VET system in Australia. The collection encompasses all delivery funded wholly or in part from public funds.

NCVER maintains a database of information on persons undertaking vocational education and training. Each state and territory collates data from their training providers on a student, course and module/unit of competency basis. These data are compiled into Australian Vocational Education and Training Management Information Statistical Standard (AVETMISS) format and validated by each training organisation before being submitted to NCVER. The data are then further validated and quality checked for inconsistencies before being used for the production of statistical reports.

Non-identification rates for Indigenous students in these data are high. Care also needs to be taken when comparing data across jurisdictions for load pass rates, as average module durations vary across jurisdictions (SCRGSP 2005b).

DEEWR Higher Education Schools Statistics Collection

The Higher Education Schools Statistics Collection comprises information on enrolments and award completions from public and private higher education institutions that are required to report to DEEWR.

Institutions receive detailed written documentation about what information is required to be furnished in the form of an electronic help file. Universities design and produce their own statistical information (enrolment) forms. These are designed to be used by institutions to collect the required information from students. DEEWR has provided institutions with suggested wording for questions relating to Indigenous status, language spoken at home and disability (ABS 2009).

Approximately 3% of students in this data collection have a ‘not stated’ Indigenous status. At the moment these are recorded as non-Indigenous, although plans are under way to record the ‘not stated’ responses separately.

2.07 Employment

The employment status of Aboriginal and Torres Strait Islander people aged 15–64 years

Data sources

Data for this measure come from the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS), the 2006 Census of Population and Housing and the Australian Bureau of Statistics Labour Force Survey.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

The labour force categories and terminologies for the 2008 NATSISS are similar to those for the 2006 Census that have been used in this measure, except that the reference periods are in relation to the 2008 NATSISS rather than the Census.

The 2008 NATSISS also collected data on Indigenous participation in the CDEP scheme:

- **Community Development Employment Projects (CDEP) scheme**—enables participants (usually members of Aboriginal or Torres Strait Islander communities) to exchange unemployment benefits for opportunities to undertake work and training in activities that are managed by a local Aboriginal or Torres Strait Islander community organisation. Participants in the program are therefore classified as employed.

Census of Population and Housing

The Census of Population and Housing is conducted by the ABS at 5-yearly intervals, and is designed to include all Australian households. The Census uses the ABS standard Indigenous status question for each household member.

Although the Census data are adjusted for undercount at the person level to arrive at the estimated resident population, no such adjustment is done at the household level. This affects the accuracy of the person counts at the household level to provide adjusted household estimates.

The 2011 Census is the most recent, however data for the Indigenous population was not yet released at the time of writing this report. Therefore data included in this report come from the 2006 Census. In 2006, the ABS enhanced the sample for the Post-Enumeration Survey to include remote areas. The measured undercount for Indigenous Australians was 11.5%.

The following labour force categories and terminologies apply to 2006 Census data:

- **Employed**—Persons aged 15 years and over who worked for payment or profit, or as an unpaid helper in a family business for a minimum of 1 hour per week, during the week before Census night. Also includes those who were absent from a job or business and Community Development Employment Projects (CDEP) participants.
- **Full-time workers**—Employed persons who reported working 35 hours or more in the week before Census night.
- **Part-time workers**—Employed persons who reported working less than 35 hours in the week before Census night.
- **Unemployed**—Persons aged 15 years who were not employed, but were actively looking for work and were available to start work, in the 4 weeks before Census night.
- **Not in the labour force**—persons who are not employed or unemployed as defined above.
- **Participation rate**—for any group, the labour force expressed as a percentage of the civilian population in the same group.
- **Employment to population ratio**—for any group, the number of employed persons expressed as a percentage of the civilian population in the same group.

2006 Census data on participation in CDEP were not available, but data on Indigenous participation in CDEP were collected as part of the 2008 NATSISS and are discussed at the end of the indicator.

ABS Labour Force Survey

The Labour Force Survey (LFS) is run monthly by the ABS and this is the main source of information about the labour force status of Australia's civilian population. From April 2001, the monthly LFS has included a question on Indigenous status. Results from the survey on Indigenous Australians are published annually by the ABS in the *Labour force characteristics of Aboriginal and Torres Strait Islander Australians, experimental estimates from the Labour Force Survey* publications, the latest of which was published in 2011. The labour force estimates for Indigenous Australians in this publication were produced by combining the LFS samples for each of the 12 months of a calendar year to produce annual estimates.

Data analyses

Comparison of NATSISS and Census data

The NATSISS and the Census collect information on the labour force status of Indigenous Australians, but the Census does not collect information on participation in Community Development Employment Projects (CDEP) from all Indigenous persons as does the NATSISS. In the Census, participation in CDEP is asked as a separate question only on the interviewer household forms and is not applicable to people enumerated on mainstream forms. Therefore, information on CDEP participation in the Census cannot be used as a count of all persons who are participating in the programs and is not presented here.

When comparing the labour force status of Indigenous persons recorded in the Census with that in the NATSISS, the results on the NATSISS were slightly higher on employment and unemployment rates. For example the proportion of Indigenous persons aged 15–64 years who were employed from the 2008 NATSISS was 54%, compared with 48% from the Census; and the proportion of Indigenous persons aged 15–64 years who were unemployed from the 2008 NATSISS was 11% compared with 9% from the Census.

This measure presents data included in the 2010 edition of this report for persons aged 15–64 years (2006 Census) and new data from the 2008 NATSISS for persons aged 15–64 years. Data from the NATSISS are presented first followed by data from the 2006 Census.

NATSISS data

- In 2008, the labour force participation rate for the Indigenous population aged 15–64 years was estimated to be 54% employed and 11% unemployed. The remaining 36% were not in the labour force (Table 2.07.1).
- After adjusting for differences in age structure, Indigenous Australians aged 15–64 years were less likely than non-Indigenous Australians to be employed (54% compared with 76%) and almost four times as likely to be unemployed (11% compared with 3%), according to the 2008 NATSISS and 2007–08 NHS data (Table 2.07.1).

Employment status by age and sex

- Indigenous Australians aged 35–44 and 45–54 years were more likely than those in all other age groups to be employed (64% and 62% respectively) (Table 2.07.1). Indigenous Australians aged 55–64 had the lowest proportion employed (39%).
- A higher proportion of Indigenous males reported they were employed than Indigenous females (63% compared with 46%) (Table 2.07.2). Indigenous males were also more likely than Indigenous females to be unemployed (12% compared with 9%).
- Based on the 2008 NATSISS and 2007–08 NHS data, Indigenous males aged 15–64 years were less likely than non-Indigenous males to be employed (63% compared with 82%). Indigenous females aged 15–64 years were also less likely than non-Indigenous females to be employed (46% compared with 70%) (Table 2.07.3).

Employment status by state/territory and remoteness

- The proportion of Indigenous Australians who were unemployed ranged from 7.2% in Tasmania to 13% in New South Wales (Table 2.07.4). The proportion of Indigenous Australians not in the labour force ranged from 20% in the Australian Capital Territory to 40% in New South Wales. The Northern Territory had the highest proportion of Indigenous Australians employed in CDEP (18%).
- In New South Wales, Victoria, Queensland, Western Australia, South Australia and Tasmania the proportion of Indigenous Australians unemployed was higher than non-Indigenous Australians. In every state and territory a higher proportion of Indigenous Australians than non-Indigenous Australians were not in the labour force (Table 2.07.5).
- Indigenous Australians in remote areas were more likely than Indigenous Australians in non-remote areas to be employed in CDEP (19% compared with 1.2%) and less likely to be employed in non-CDEP (33% compared with 53%) (Table 2.07.6).
- Indigenous Australians in non-remote areas were more likely to be unemployed than Indigenous Australians in Remote areas (11% and 9.2% respectively) (Table 2.07.7).

Employment status by summary health characteristics

The 2008 NATSISS collected information on the labour force status and selected health characteristics of Indigenous Australians. Results are shown in tables 2.07.8 and 2.07.9.

- In 2008, of the Indigenous Australians aged 15–64 years who reported they had excellent health, approximately 60% were employed, 12% unemployed and 29% were not in the labour force. Further, of the Indigenous Australians aged 15–64 who reported poor health, 24% were employed, 10% were unemployed and 66% were not in the labour force (Table 2.07.8).
- In 2008, for Indigenous Australians aged 15–64 years both employed and unemployed most commonly reported good health (35% and 34% respectively) while more unemployed Indigenous Australians reported poor health than employed Indigenous Australians (6.2% and 2.8% respectively) (Table 2.07.9).

Table 2.07.8: Labour force status of Indigenous persons aged 15–64 years, by summary health characteristics, 2008

Preferred working hours

- During 2008, 35% of Indigenous Australians aged 15–24 years would have liked more hours at their current workplace and only 6% would have liked fewer hours than they were currently working. This is compared with older age groups that showed a steady decrease in those who would like more hours and an increase in those who would like less hours. For those aged 55–64 years, 23% of Indigenous persons would have liked fewer hours and 14% would have liked more hours (Table 2.07.10).

Commencement and duration of paid employment

- In 2008, 84% of 55–64 year old Indigenous Australians had been in their current employment for two years or more, compared with only 26% of 15–24 year old Indigenous Australians. Among those aged 15–24 years, Indigenous males (33%) were more likely to have been employed for over two years than Indigenous females (26%) (Table 2.07.11).
- In 2008, the percentage of Indigenous Australians who started their first paid employment between the ages 15 and 19 years ranged from 95% in the Australian Capital Territory to 75% in the Northern Territory. In Australia overall, 89% of Indigenous Australians had begun their first paid employment by the age of 19 years (Table 2.07.12).
- For Indigenous Australians, the amount of time employed throughout their lifetime varied by jurisdiction. The percentage of Indigenous Australians employed for 25 years or more ranged from 15% in the Northern Territory to 26% in the Australian Capital Territory (Table 2.07.13).

Census data

Employment status by age and sex

- In 2006, Indigenous Australians had a 54% labour force participation rate, compared with 75% for non-Indigenous Australians (Table 2.07.14).
- Indigenous Australians had an employment to population ratio of 0.5, compared with the non-Indigenous ratio of 0.7 (Table 2.07.15).

Table 2.07.14: Age-specific labour force participation rates, by Indigenous status, 2006

	15–24	25–34	35–44	45–54	55–64	Total age-standardised
Indigenous	48	58	60	59	38	54
Non-Indigenous	66	82	82	82	57	75

Note: Total directly age-standardised using the Australian 2001 standard population.

Employment by sector, hours worked and occupation

- In 2006, approximately 59% of Indigenous persons aged 15–64 years employed in the labour force were working full-time compared with 69% of non-Indigenous persons of the same age (Table 2.07.16).
- Around three-quarters (74%) of Indigenous employed persons were working in the private sector, 12% were working for state/territory government, 10% were working for local government and 4% were working for the Commonwealth Government. In comparison, approximately 85% of non-Indigenous persons were working in the private sector, 9% in state/territory government, 1% in local government and 4% in the Commonwealth Government (Table 2.07.16).
- In 2006, the most common occupations for Indigenous employed persons were labourers (24%), community and personal service workers (16%), and clerical and administrative workers (13%). For non-Indigenous employed persons the most common occupations were professionals (20%), clerical and administrative workers (15%) and technicians and trades workers (15%) (Table 2.07.16).

Table 2.07.16: Employed persons aged 15–64 years, by hours worked, sector and occupation, 2006

	Number		Proportion	
	Indigenous	Non-Indigenous	Indigenous	Non-Indigenous
Hours worked				
Employed, worked full-time	64,693	5,629,054	59.2	69.1

ABS Labour Force Survey data

Time series analyses

- Data from the ABS Labour Force Survey over period 2005 to 2011 indicates that after a decrease in Indigenous unemployment from 9.2% in 2005 to 8.3% in 2008, unemployment increased to 11% in 2009 and 2010, and then decreased again to 9.4% in 2011. Minor changes in employment and those not in the labour force occurred over the same period (Table 2.07.17).

Table 2.07.17: Labour force status of Indigenous persons aged 15–64 years, 2005 to 2011 (per cent)

Year	Employed	Unemployed	Not in the labour force	Total
2005	49.7	9.2	41.1	100.0
2006	52.5	8.4	39.1	100.0
2007	50.4	8.1	41.5	100.0
2008	49.6	8.3	42.2	100.0
2009	47.6	10.5	41.9	100.0

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: User's guide 2008* (ABS 2010).

Census of Population and Housing

The Census uses the National health data dictionary standard Indigenous status question and it is asked for each household member. Measures that are drawn from Census data are subject to broad data concerns relating to the unexplained growth in the Aboriginal and

Torres Strait Islander population since the 1991 Census, and the limitations of self-identification. Other Census data issues relate to the accuracy of the Census count itself; for example, whether people are counted more than once, or are undercounted (ABS 1996).

Although the Census data are adjusted for undercounts at the person level to arrive at the estimated resident population, no such adjustment is done at the household level. This affects the accuracy of the person counts at the household level to provide adjusted household estimates.

ABS Labour Force Survey

The ABS monthly Labour Force Survey (LFS) included a question on Indigenous status from April 2001. The reliability of estimates from the survey is affected by the relatively small size of the Indigenous population, the small number of Indigenous persons in the LFS sample, and particular collection difficulties in remote areas (ABS 2011). Indigenous estimates from the LFS have methodological and definitional differences from other sources such as the Census of Population and Housing. The differences in the methodologies used affect the comparability of the data.

Results from the survey on Indigenous Australians are published annually by the ABS in the *Labour force characteristics of Aboriginal and Torres Strait Islander Australians, experimental estimates from the Labour Force Survey* publications. The methodology used to produce the labour force estimates for Indigenous Australians is based on combining the LFS samples for each of the twelve months of the year. This pooling has resulted in a sample of between 10,500 and 14,200 records each year. This sample size is adequate for providing broad aggregates of labour force characteristics at the state and territory level. However, the sample size per year is still quite small, resulting in constraints on the level of disaggregated data available from the survey.

The ABS considers the estimates of the Indigenous labour force experimental because of the experimental nature of the Indigenous population projections used in producing these estimates and the small sample of Indigenous people in the LFS.

All LFS estimates are subject to sampling errors. This is particularly relevant to these Indigenous estimates because of the small size of the Indigenous population and the small number of Indigenous persons in the LFS sample. These estimates are also subject to non-sampling errors due to particular collection difficulties in remote areas, in addition to imperfections in reporting, recording or processing of data that can occur in any survey or census.

It is also important to note that the population benchmarks used for compiling Indigenous labour force estimates are not predictions or forecasts, but are projections of 2006 Census data reflecting the growth in population which would occur if certain assumptions about future levels of fertility, mortality, migration and unexplained growth were to prevail over the projection period (ABS 2012).

List of tables

2.08 Income

Equivalised gross household and individual income of Aboriginal and Torres Strait Islander people

Data sources

Data for this measure come from the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS), and the 2007– 2008 Survey of Income and Housing (SIH).

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of areas of social concern including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Survey of Income and Housing (SIH)

The Survey of Income and Housing (SIH) is conducted by the ABS every two years, with the first survey beginning in 1994–95. The survey was developed in order to provide broad aggregates for households within Australia. The current survey was conducted during the period of August 2007 and June 2008 and 9,345 households participated through a personal interview at their usual place of residence. The dwellings were selected through a stratified, multistage cluster design and the survey was conducted over 12 months to be representative of a yearly pattern. Participants were asked information regarding their household, including characteristics, costs, assets and liabilities and individual personal characteristics for residents over 15 years.

Very remote areas were not covered by the survey.

Data analyses

NATSISS and SIH data

Household income

Mean equivalised household income

Data on the mean equivalised household income of Indigenous and non-Indigenous persons are available from the 2008 NATSISS and 2007–08 SIH respectively.

- The 2008 NATSISS estimated that the mean equivalised gross household income was $580 per week for Indigenous persons aged 18 years and over compared with $983 per week for non-Indigenous persons according to the 2007–08 SIH estimate (Table 2.08.1).
- The mean equivalised gross household income for Indigenous persons varied by state and territory, ranging from $489 per week in the Northern Territory to $990 per week in the Australian Capital Territory (Table 2.08.1).
- The largest difference in the mean equivalised gross weekly household income of Indigenous Australians by remoteness was between *Major cities* ($678) and *Very remote* areas ($469) (Table 2.08.2).

Table 2.08.1: Mean equivalised gross household income ($ per week), by Indigenous status and state/territory, persons aged 18 years and over, 2008

Equivalised household income quintiles/percentiles

Data on equivalised household income quintiles and percentiles are presented below.

- In 2008, of those who stated their household income, approximately 49% of Indigenous Australians aged 18 years and over were in the lowest (1st) quintile of equivalised gross weekly household income compared with 20% of non-Indigenous Australians. Only 4.9% of Indigenous Australians were in the highest quintile of equivalised gross weekly household income compared with 22% of non-Indigenous Australians (Table 2.08.3).
- In 2008, 41% of Indigenous Australians aged 18 years and over living in *Major cities* were in the lowest quintile of equivalised gross weekly household income compared with 62% of Indigenous Australians in *Very remote* areas. Around 15% and 7% of Indigenous Australians in *Major cities* were in the fourth and highest quintiles of income respectively compared with 5% and 3% of Indigenous Australians in *Very remote* areas (Table 2.08.4).

Table 2.08.3: Proportion of persons aged 18 years and over in equivalised gross weekly household income quintiles, by Indigenous status, 2008

Quintiles	Indigenous	Non-Indigenous
Lowest	49.2*	19.8

* Difference between Indigenous and non-Indigenous rates is statistically significant at the $p < 0.05$ level for these categories.

(a) Equivalised gross household income quintile boundaries for Indigenous persons (NTSISS 2008) are: first (0 to $435); second ($436 to $686); third ($687 to $952); fourth ($953 to $1380); and fifth ($1,381 or more).

(b) Equivalised gross household income quintile boundaries for non-Indigenous persons (SIH 2007–08) are: first (0 to $423); second ($424 to $666); third ($667 to $925); fourth ($926 to $1,341); and fifth ($1,342 or more).

(c) Comprises persons living in households where household income was stated. Note that equivalised gross weekly household income quintiles are calculated as a proportion of households with stated household income.

(d) Estimate has a relative standard error between 25% and 50% and should be used with caution.

Equivalised household income quintiles/percentiles by state/territory

Data presented below on equivalised household income quintiles and percentiles are from NATSISS 2008.

- There has been a change in the mean equivalised gross household income for Indigenous persons between 1994 and 2008. Nationally, the mean equivalised gross household income was $445 in 1994, increasing to $469 in 2002, and $580 in 2008 (Table 2.08.5).
- New South Wales had the highest proportion of Indigenous Australians in the lowest quintile of equivalised gross weekly household income (43%) and Western Australia had the highest proportion of Indigenous Australians in the highest income quintile (6%) (Table 2.08.6).
- In 2008, the Northern Territory had the highest proportion of Indigenous Australians aged 18 years and over below the 20th percentile (60%) and 50th percentile (84%) of equivalised gross weekly household income, compared with 48% and 87% respectively in 2002. In 2008, Tasmania and the Australian Capital Territory had the lowest proportions, 41% and 71%, respectively (Table 2.08.7).

(a) Equivalised gross household income quintile boundaries for Indigenous persons are: first (0 to $435); second ($436 to $686); third ($687 to $952); fourth ($953 to $1380); and fifth ($1,381 or more).

Notes

1. Excludes those for whom income was unknown or not stated.
2. Significant test are for the changes between 2002 and 2008 for indicator "below 20th percentile" and "below 50th percentile".

Source: AIHW analyses of 2008 NATSISS and 2002 NATSISS.

Individual income

As with the gross weekly equivalised household income, the individual income quintile boundaries are based on the total population as derived from the 2007–08 SIH and have been applied to both the Indigenous and non-Indigenous populations.

- In 2008, Indigenous people aged 18 years and over were more likely to be in the three lowest individual income quintiles, and the difference between Indigenous and non-Indigenous people was statistically significant for all quintiles. Only 8% of Indigenous Australians aged 18 years and over were in the highest individual income quintile compared with 21% of non-Indigenous Australians (Table 2.08.8).

Table 2.08.8: Gross weekly Individual income quintiles by Indigenous status, persons aged 18 years and over, 2008

Income quintile	Indigenous (per cent)	Non-Indigenous (per cent)
Lowest	25.3*	16.2
Second	26.5*	20.5
Third	24.6*	21.2
Fourth	15.8*	20.9
Highest	7.8*	21.2
Total[(a)]	**100.0**	**100.0**
Total number[(a)]	**275,781**	**15,495,581**

* Difference between Indigenous and non-Indigenous rates is statistically significant at the $p < 0.05$ level for these categories.

(a) Total excludes not stated or not known responses.

Source: NATSISS 2008 and SIH 2007–08.

Equivalised household income by summary health and population characteristics

- Indigenous Australians with fair/poor self-assessed health status were more likely to be in the lowest quintile of household income than those with excellent/very good health status (Table 2.08.9).
- Indigenous Australians whose highest year of schooling completed was Year 12 or who had a non-school qualification were more likely to be in the fourth or fifth quintiles of household income than those who reported Year 9 or below as their highest year of schooling or did not have a non-school qualification (Table 2.08.9).
- Indigenous Australians who were employed or homeowners were also more likely to be in the fourth or fifth quintiles of household income than those who were unemployed or renters (Table 2.08.9).
- Indigenous Australians in the lowest income quintile were much more likely to be renters (83%) than home owners (15%) (Table 2.08.10).

Additional information

Financial stress

The 2008 NATSISS collected information on whether Indigenous households could raise $2,000 in an emergency, and whether the household had days without money for basic living expenses in the 2 weeks before the survey and in the 12 months before the survey.

- In 2008, approximately 47% of Indigenous Australians aged 15 years and over were living in households which reported they could not raise $2,000 within a week in a time of crisis. Indigenous people in remote areas were more likely to report that they could not raise $2,000 within a week than Indigenous people in *Major cities* and *Regional* areas (64% compared with 40% and 43% respectively).
- Around one-quarter (28%) of Indigenous persons aged 15 years and over reported they had days without money for basic living expenses in the 12 months before the survey.
- Indigenous Australians who reported they were unable to raise $2,000 within a week for something important or had days without money for basic living expenses in the 2 weeks or 12 months before the survey were more likely to be in the lowest quintile of household income than in the higher income quintiles.

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010).

Survey of Income and Housing (SIH)

Survey data are subject to sampling and non-sampling errors. Non-sampling errors can occur in surveys owing to questionnaire design problems, respondent difficulty recalling information/lack of appropriate records, and errors made in the recording and processing of the data. Every effort was made to minimise non-sample errors in this survey. However, the survey's had a sample loss and non-response of 1,781 dwellings, 16% of the selected sample and 2,026 households having at least one imputed value in income or child care expenses.

List of Tables

2.09 Index of disadvantage

An analysis of the relative disadvantage within the Aboriginal and Torres Strait Islander population compared with the non-Indigenous population

Data sources

Data for this measure come from the 2006 Census of Population and Housing.

Census of Population and Housing

The Census of Population and Housing is conducted by the ABS at 5-yearly intervals, and is designed to include all Australian households. The Census uses the ABS standard Indigenous status question for each household member.

Although the Census data are adjusted for undercount at the person level to arrive at the estimated resident population, no such adjustment is done at the household level. This affects the accuracy of the person counts at the household level to provide adjusted household estimates.

The 2011 Census is the most recent, however data for the Indigenous population was not yet released at the time of writing this report. Therefore data included in this report come from the 2006 Census. In 2006, the ABS enhanced the sample for the Post-Enumeration Survey to include remote areas. The measured undercount for Indigenous Australians was 11.5%.

Socioeconomic Indexes for Areas (SEIFA)

The ABS has developed four indexes to allow measurement of relative socioeconomic status at a small area level. These indexes summarise a range of socioeconomic variables associated with disadvantage. Each index summarises a different aspect of the socio-economic conditions of people living in an area. They each summarise a different set of social and economic information. The indexes take into account a range of factors in determining socio-economic conditions.

Index of Advantage/Disadvantage

This index is a continuum of advantage to disadvantage and is available for both urban and rural areas. Low values indicate areas of disadvantage, and high values indicate areas of advantage. It takes into account variables such as the proportion of families with high incomes, people with a tertiary education, and employment in skilled occupations (ABS 2003).

The Census does not collect all of the variables identified as being related to socioeconomic status. Some of the variables may be context-specific and some are associated with age (e.g. income), yet the methodology does not allow for age-standardisation. This is particularly relevant in the context of this performance measure where we are comparing two populations that have different age structures.

Data analyses

Following the concepts and methodology of the Index of Relative Socio-Economic Advantage and Disadvantage (IRSAD), persons surveyed were ranked according to their IRSAD and then split into deciles or quintiles based on total population.

SEIFA

- In 2006, Indigenous Australians are over-represented in the three most disadvantaged deciles; for example, 31% of the Indigenous population were in the most disadvantaged decile compared with 10% of the non-Indigenous population (Table 2.09.1; Figure 2.09.1).
- Less than 2% of the Indigenous population were in the most advantaged decile compared with 10% of the non-Indigenous population (Table 2.09.1; Figure 2.09.1).

Table 2.09.1: Population distribution by SEIFA advantage/disadvantage decile, by Indigenous status, 2006

	Indigenous population	Non-Indigenous population	Total population
		Per cent	
Decile 1 (most disadvantaged)	31.2	9.5	10.0
Decile 2	15.1	9.8	9.9
Decile 3	11.5	10.0	10.1
Decile 4	10.4	10.0	10.0
Decile 5	9.2	10.0	10.0
Decile 6	8.0	10.0	10.0
Decile 7	5.3	10.1	10.0
Decile 8	5.1	10.2	10.1
Decile 9	2.8	10.0	9.8
Decile 10 (most advantaged)	1.5	10.4	10.2

Source: AIHW analysis of 2006 Census data.

Figure 2.09.1: Population distribution by SEIFA advantage/disadvantage decile, by Indigenous status, 2006

SEIFA by state/territory

- In 2006, in all states and territories a greater proportion of the Indigenous population were in the most disadvantaged quintile compared with the non-Indigenous population. The Northern Territory had the highest proportion (58%) (Table 2.09.4; Figure 2.09.4) and the Australian Capital Territory had the lowest proportion (27%) of the Indigenous population in the most disadvantaged quintile (Table 2.09.3; Figure 2.09.3).
- New South Wales had the lowest proportion (3%) and the Australian Capital Territory had the highest proportion (10%) of the Indigenous population in the most advantaged quintile (Tables 2.09.2 and 2.09.4; Figures 2.09.2 and 2.09.3).

Table 2.09.2: Population distribution by SEIFA advantage/disadvantage quintiles, by Indigenous status, NSW, Vic & Qld, 2006

	Indigenous population	Non-Indigenous population	Total population
		New South Wales	
Quintile 1 (most disadvantaged)	42.9	19.5	20.1
Quintile 2	24.8	20.0	20.2
Quintile 3	18.9	19.7	19.7
Quintile 4	9.7	20.4	20.2
Quintile 5 (most advantaged)	3.4	19.7	19.3
		Victoria	
Quintile 1 (most disadvantaged)	40.1	19.7	19.9
Quintile 2	25.9	19.5	19.6
Quintile 3	16.7	20.2	20.2
Quintile 4	10.7	19.8	19.8
Quintile 5 (most advantaged)	6.7	20.7	20.6
		Queensland	
Quintile 1 (most disadvantaged)	45.9	19.0	19.9
Quintile 2	25.6	20.0	20.2
Quintile 3	14.0	20.4	20.2
Quintile 4	9.4	20.4	20.1
Quintile 5 (most advantaged)	5.3	20.3	19.8

Note: The population of some states/territories was unable to be split into exact quintiles based on the SEIFA index of advantage/disadvantage. In all except one of these cases, the best approximate quintiles were calculated. Approximate population quintiles based on the SEIFA index of advantage/disadvantage were unable to be calculated for Tasmania because of the population spread.

Data quality issues

Census of Population and Housing

The Census uses the National health data dictionary standard Indigenous status question and it is asked for each household member. Measures that are drawn from Census data are subject to broad data concerns relating to the unexplained growth in the Aboriginal and Torres Strait Islander population since the 1991 Census, and the limitations of self-identification. Other Census data issues relate to the accuracy of the Census count itself; for example, whether people are counted more than once, or are under-counted (ABS 1996).

Although the Census data are adjusted for under-counts at the person level to arrive at the estimated resident population, no such adjustment is done at the household level. This affects the accuracy of the person counts at the household level to provide adjusted household estimates.

Socioeconomic Indexes for Areas (SEIFA)

There are a range of data items that can be included in an index on socioeconomic disadvantage and the Census does not collect all of the variables identified as being related to socioeconomic status. Some of the variables may be context-specific (e.g. a low mortgage in Sydney may be high in another city) and some are associated with age (e.g. income), yet the methodology does not allow for age-standardisation. This is particularly relevant in the context of this performance measure where we are comparing two populations that have different age structures.

Analysis of SEIFA results at small area levels has found that within any area there will be individuals and subpopulations with very different characteristics from the overall population of the area. When judgments are made about the individual or subpopulation based on the characteristics of the area, there is considerable potential for error (Baker & Adhikari 2007). This issue is particularly relevant for the Indigenous population, because they make up a small proportion of the population in most areas of Australia.

Kennedy and Firman (2004) found that the traditional approach to analysing SEIFA at an area level masks the socioeconomic status of Indigenous Australians who make up a small proportion of most areas. They found that stratifying SEIFA scores by Indigenous and non-Indigenous households in each area shows that Indigenous populations suffer a high level of social and economic disadvantage, regardless of whether they live in high or low socioeconomic areas.

List of tables

List of figures

2.10 Community safety

Three parameters of community safety are considered for this measure:

1. **experience of personal injury or death as a result of violence**
2. **experience of threatened violence or a social setting in which violence is common**
3. **experience of a social setting where there is a lack of security and a perception of danger; for example, where crimes against property or disorderly behaviour are common**

Data sources

Data for this measure come from the National Aboriginal and Torres Strait Islander Social Survey, the Australian Institute of Health and Welfare (AIHW) National Hospital Morbidity Database, the AIHW National Mortality Database and the Australian Institute of Criminology (AIC) National Homicide Monitoring Program.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and ACT (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

National Mortality Database

The National Mortality Database is a national collection of de-identified unit record level data. It comprises most of the information recorded on death registration forms and medical (cause of death) certificates, including Indigenous status. The database is maintained by the Australian Institute of Health and Welfare (AIHW). Information on the characteristics and causes of death of the deceased is provided by the Registrars of Births, Deaths and Marriages and coded nationally by the Australian Bureau of Statistics (ABS). Information on the cause of death is supplied by the medical practitioner certifying the death, or by a coroner. The data are updated each calendar year and are presented by state/territory of usual residence rather than state/territory where death occurs.

It is considered likely that most deaths of Aboriginal and Torres Strait Islander people are registered. However, a proportion of these deceased are not reported as Aboriginal or Torres Strait Islander by the family, health worker or funeral director during the death registration process. That is, while data are provided to the ABS for the Indigenous status question for 99% of all deaths, there are concerns regarding the accuracy of the data. The Indigenous status question is not always directly asked of relatives and friends of the deceased by the funeral director.

While the identification of Indigenous Australians in deaths data is incomplete in all state and territory registration systems, 5 jurisdictions (New South Wales, Queensland, Western

Australia, South Australia and the Northern Territory) have been assessed by the ABS and the AIHW as having adequate identification. Longer term mortality trend data are limited to 3 jurisdictions (Western Australia, South Australia and the Northern Territory) with adequate identification of Indigenous deaths in their recording systems from 1991 onwards. The quality of the time-series data is also influenced by the late inclusion of a not stated category for Indigenous status in 1998. Prior to this time, the not stated responses were probably included with the non-Indigenous.

Deaths registered in 2010 with a usual residence of Queensland have been adjusted to exclude deaths registered in 2010 that occurred prior to 2007. This is to minimise the impact of late registration of deaths due to recent changes in the timeliness of death registrations in Queensland.

Western Australian Aboriginal and Torres Strait Islander deaths for 2007, 2008 and 2009, have been revised to correct for a data quality issue which resulted in the over-reporting of Indigenous deaths during this period.

Deaths for which the Indigenous status of the deceased was not reported have been excluded from the analysis.

Data have been combined for the 5-year period 2006–2010 because of the small number of deaths from some conditions each year. Data have been analysed using the year of registration of death for all years.

National Homicide Monitoring Program

The Australian Institute of Criminology collects data on all homicides recorded in Australia under the National Homicide Monitoring Program (NHMP). The NHMP was established in 1990 and reports annually by financial year on all homicides recorded in Australia. The Indigenous status of the victim is based on police identification of 'racial appearance' and therefore will under-estimates the level of homicide involving Indigenous persons. Nevertheless, the NHMP includes useful information on the circumstances surrounding homicides involving Indigenous persons, such as motive for killing, and victim and perpetrator relationship.

Data analyses

Age-standardised rates and ratios have been used where appropriate as a measure of the Indigenous population relative to other Australians. Ratios of this type illustrate differences between the rates among Indigenous people and those of other Australians, taking into account differences in age distributions.

Self-reported data

The 2008 NATSISS collected information on issues of community safety, being witness and victim to violence, physical and threatened violence, personal stressors experienced in the 12 months before the survey and neighbourhood community problems. This information is presented below, as well as (where appropriate) data from the NHS 2007–08 to provide a comparison with the non-Indigenous population.

Issues of community safety

- In the last 12 months prior to the surveys, 79% of Indigenous Australians and 49% of non-Indigenous Australians aged 18 years and over reported experiencing a stressor relating to community safety; 21% of Indigenous Australians and 11% of non-Indigenous Australians aged 18 years were victims of physical or threatened violence (Table 2.10.2).
- The stressor most likely to be experienced related to the death of a family member or close friend, which was reported by 40% of Indigenous people and 19% of non-Indigenous people. This made the greatest rate difference between Indigenous and non-Indigenous Australians.
- Twenty four per cent of Indigenous people and 6% of non-Indigenous people reported experiencing a stressor related to alcohol or drug-related problems, and 17% of Indigenous people and 9% of non-Indigenous people experienced a stressor related to mental illness.
- The greatest relative disparity of experienced stressors between Indigenous and non-Indigenous Australians was for stressors related to trouble with the police, for which Indigenous Australians reported at 5.6 times the rate for non-Indigenous, followed by alcohol or drug-related problems (4.2) and witness to violence (4.0) (Tables 2.10.2). The greatest absolute disparity was for death of a family member or friend (difference of 21%), followed by alcohol or drug-related problems (difference of 19%).

Issues of community safety and personal stressors by age

- In the last 12 months prior to the surveys, Indigenous Australians of all age groups over 18 years were more likely to have experienced a stressor related to community safety than non-Indigenous Australians. The rate ratios were similar across all age groups (1.5 to 1.7) (Table 2.10.1).
- For Indigenous Australians, the proportions experiencing stressors were similar for all age groups (ranged from 77% to 80%).

Issues of community safety and personal stressors by sex

- The proportions experiencing stressors for Indigenous males and females were similar (78% and 80%), while non-Indigenous females were more likely than non-Indigenous males to have experienced a stressor (53% compared to 46%) (Table 2.10.2).

Issues of community safety and personal stressors by state/territory

- In 2008, the proportions of Indigenous persons over 18 years of age reporting experiencing stressors in the 12 months prior to the surveys ranged from 72% in the Northern Territory to 83% in Victoria. For non-Indigenous Australians, the proportions ranged from 48% in New South Wales to 52% in the Australian Capital Territory (Table 2.10.3).

Issues of community safety and personal stressors by remoteness

- In 2008, the proportion of Indigenous Australians aged 18 years and over experiencing a stressor in the previous 12 months was highest in *Major cities* (82%) and lowest in *Very remote* areas (72%) (Table 2.10.4). For non-Indigenous Australians, the proportion was highest in *Inner regional* areas (51%) and lowest in *Outer regional* areas (47%).

*Difference between rates for Indigenous and non-Indigenous persons are statistically significant at the p<0.05 level for these categories

(a) For this variable only, non-Indigenous comparison has been sourced from General Social Survey 06 (GSS06). Totals are age-standardised, as this measure was found to be associated with age.

(b) In the 2008 NATSISS, Indigenous persons were asked about 24 separate stressors, and in the 2007–08 NHS, non-Indigenous persons were asked about 14 separate stressors.

(c) Sum of components may exceed total, as persons may have reported more than one type of stressor.

(d) Includes all other types of stressors not listed here

Note: Excludes stressors not stated

Sources: ABS analysis of NATSISS 2008 and NHS 07–08.

(a) In the 2008 NATSISS, Indigenous persons were asked about 24 separate stressors, and in the 2007–08 NHS, non-Indigenous persons were asked about 14 separate stressors.

(b) Estimate has a relative standard error between 25% and 50% and should be used with caution.

(c) Estimate has a relative standard error greater than 50% and is considered too unreliable for general use.

(d) Sum of components may be more than total, as persons may have reported more than one type of stressor.

(e) Includes all other types of stressors not listed here.

Note: Excludes stressors not stated.

Sources: NATSISS 2008 and NHS 07–08.

Victim of physical or threatened violence

- In 2008, 25% of Indigenous Australians aged 15 years and over reported they were a victim of physical or threatened violence in the previous 12 months. This is similar to the proportion of Indigenous Australians aged 15 years and over who reported they were a victim of physical or threatened violence in the previous 12 months in 2002 (24%) (Table 2.10.5).

Victim of physical or threatened violence, by sex

- In 2008, the proportion of Indigenous males aged 15 years and over who reported they were a victim of physical or threatened violence was similar to the proportion of Indigenous females (24% and 25% respectively).

Table 2.10.5: Proportion of Indigenous persons aged 15 years and over reporting they were victims of physical or threatened violence in previous 12 months, by sex, 2002 and 2008

	Males	Females	Total
2002	25.7	23.1	24.3
2008	24.3	24.7	24.5

Note: A change in methodology between 2002 and 2008 may affect comparison of this data.

Victim of physical or threatened violence, by remoteness

- In 2008, the proportion of Indigenous Australians aged 15 years and over who reported they were a victim of physical or threatened violence in the previous 12 months varied by remoteness. The highest proportion was in *Major cities* (26%) and the lowest proportion was in *Very remote* areas (20%) (Table 2.10.6).

Table 2.10.6: Proportion of Indigenous persons aged 15 years and over reporting they were a victim of physical or threatened violence in previous 12 months[(a)], by remoteness, 2008

Victim of physical or threatened violence, by selected population characteristics

- In 2008, Indigenous Australians with a disability or long-term health condition were more likely to have been a victim of physical or threatened violence than those with no disability (29% compared with 21%) (Table 2.10.7).
- Indigenous persons aged 15 years and over in the first quintile of disparity index (most disadvantaged) were more like to have been a victim of physical or threated violence than those in the fifth quintile (least disadvantaged) (24% compared to 19%). House renters were more like to have been a victim of physical or threated violence than house owners (27% compared to 19%).
- Nearly 40% of Indigenous persons aged 15 years and over who were removed from natural family were a victim of physical or threated violence in the 12 months prior to the survey.

Victim of and witness to violence by selected health and population characteristics

Tables 2.10.8, 2.10.9 and 2.10.10 present data on whether Indigenous persons were a victim of, or were a witness to violence by selected health and population characteristics. Table 2.10.8 and 2.10.9 both present data for Indigenous and non-Indigenous Australians however percentages are calculated using different totals as the denominator. Proportions in Table 2.10.8 are calculated within a column using the total of the rows as the denominator; while proportions in Table 2.10.9 are calculated within a row using the total of the columns as the denominator. Table 2.10.10 presents data for Indigenous persons only and compares those who witness violence to those that did not.

- In 2008, of the Indigenous Australians aged 18 years and over who reported that they or their family members or close friends witnessed violence, 71% had a disability or long-term health condition, 54% were in the first (lowest) quintile of the index of disparity, 56% were under financial stress and 74% lived in non-remote areas (Table 2.10.8).
- Indigenous Australians who had witnessed violence were twice as likely to report fair/poor health as non-Indigenous persons who had witnessed violence (Table 2.10.8).
- Indigenous persons with a disability or long-term health condition were more likely to have witnessed violence than those who did not have a disability or long-term health condition (12% compared to 6%). Indigenous renters were more likely to have witnessed violence that Indigenous home owners (10% compared to 7%) (Table 2.10.9).
- In 2008, Indigenous persons aged 18 years and over who witnessed violence were more likely than Indigenous persons of the same age who did not witness violence to report fair or poor health, be in the lowest income quintile, live in remote areas, be arrested by the police in the last 5 years and to have been removed or had a relative removed from their natural family (Table 2.10.10).

Neighbourhood/community problems

In the 2008 National Aboriginal and Torres Strait Islanders Social Survey, Indigenous Australians aged 15 years and over were asked if they thought that there were any problems as listed in Tables 2.10.11 to 2.10.14 in the community or neighbourhood. Tables 2.10.11 to 2.10.14 present for each listed problem the proportions of Indigenous population aged 15 years and over who reported that their community/neighbourhood had the problem by age group, sex, state/territory, and remoteness.

- In 2008, 74% of Indigenous Australians aged 15 years and over thought that neighbourhood or community problems were present in their neighbourhood/community (Table 2.10.11).
- Dangerous or noisy driving was the most common neighbourhood/community problem reported (46%), followed by theft (43%). Problems involving youth, vandalism/graffiti/damage to property, alcohol and illegal drugs were also common problems reported.

Neighbourhood/community problems by age

- The proportion of Indigenous Australians who thought that neighbourhood/community problems existed was lowest among those aged 55 years and over (68%) and highest among those aged 35–44 (78%) (Table 2.10.11).

Table 2.10.11: Neighbourhood/community problems, Indigenous persons aged 15 years and over, by age group, 2008

Neighbourhood/community problems by sex

- In general, the proportion of Indigenous males thinking that neighbourhood/community problems existed was similar to the proportion of females (73% and 75% respectively) (Table 2.10.12).
- Indigenous females had a higher proportion that reported problems with neighbours as a neighbourhood/community problem than Indigenous males (17% compared to 14%).

Neighbourhood/community problems by state/territory

- In general, for all states and territories, the proportions of Indigenous persons aged 15 years and over thinking that neighbourhood/community problems existed were similar, ranging from 71% (Queensland) to 77% (New South Wales) (Table 2.10.13).
- For each of the listed neighbourhood/community problems, the proportions varied with state/territory. Nearly half (49%) of Indigenous persons aged 15 years and over in New South Wales thought that theft was a neighbourhood/community problem, while the proportion in the Northern Territory was 34%. Nearly 14% of Indigenous persons aged 15 years and over in New South Wales reported sexual assault as a neighbourhood/community problem, but the proportion in the Australian Capital Territory and Tasmania combined was 5%.

Neighbourhood/community problems by remoteness

- In general, the proportions of Indigenous persons aged 15 years and over reporting neighbourhood/community problems for remote and non-remote areas were similar (76% and 73% respectively) (Table 2.10.14).
- However, for some of the neighbourhood/community problems, the proportions in remote areas were very different from that in non-remote areas. For example, in remote areas, 37% Indigenous persons aged 15 years and over reported assault as a neighbourhood/community problem, which was almost twice the proportion in non-remote areas (19%).

Table 2.10.14: Neighbourhood/community problems, Indigenous persons aged 15 years and older, by remoteness, 2008

Neighbourhood/community problems by selected health and population characteristics

Table 2.10.15 present the proportion of Indigenous persons aged 15 years and over reporting neighbourhood/community problems by selected health and population characteristics.

- In 2008, around one-third (33%) of Indigenous persons who reported family violence as a neighbourhood/community problem currently lived in their homelands; 11% had been removed from their natural family; 76% were home owners and 51% were in the lowest income quintile. These proportions were similar for Indigenous persons who reported assault, sexual assault or personal safety as a neighbourhood/community problem.

Table 2.10.15: Proportion of Indigenous persons aged 15 years and over reporting neighbourhood/community problems by selected health and population characteristics, 2008

Hospitalisations

- For the period July 2008 to June 2010, there were 10,606 hospitalisations of Indigenous Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, in which assault was recorded as the principal diagnosis (Table 2.10.16). This represented approximately 2% of total hospitalisations of Indigenous Australians in these states and territories.
- Indigenous Australians were hospitalised for assault at a rate of 10.7 per 1,000 population, while non-Indigenous Australians were hospitalised for assault at 0.9 per 1,000 population. This was a difference of 9.8 hospitalisations per 1,000 population and indicates that Indigenous Australians were hospitalised for assault at over 12 times the rate of non-Indigenous Australians.

Hospitalisations by age and sex

- The hospitalisation rate for assault was highest for the age group 25–34 for the Indigenous population (23 per 1,000 population), followed by the 35–44 age group (21 per 1,000). For non-Indigenous Australians, the highest rate was for the 15–24 age group (2.2 per 1,000), followed by the 25–34 age group (1.6 per 1,000) (Table 2.10.16).
- Indigenous males and females were hospitalised for assault at similar rates (10.9 and 10.6 per 1,000 respectively). While the rate difference between Indigenous and non-Indigenous was similar for males and females (9.4 and 10.3 per 1,000 respectively), the rate ratio was much higher for females (34.4) than for males (7.5).
- The age-groups with the largest disparity in hospitalisation rates for assault were 25–34, 35–44 and 45–54 years (rate differences of 22, 20 and 11 per 1,000 respectively). Indigenous males in the age groups 35–44, 45–54 and 55–64 age groups were hospitalised for assault at over 10 times the rate of non-Indigenous males in those age groups. Indigenous females aged 25–34 and 35–44 years were hospitalised for assault at over 40 times the rate of non-Indigenous females.

Table 2.10.16: Hospitalisations with a principal diagnosis of injury and poisoning and a first reported external cause of assault, by Indigenous status, sex and age, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010 (a)(b)(c)(d)

Table 2.10.16 (continued): Hospitalisations with a principal diagnosis of injury and poisoning and a first reported external cause of assault, by Indigenous status, sex and age, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010 (a)(b)(c)(d)

* Represents results with statistically significant differences at the p<0.05 level in the Indigenous/non-Indigenous comparisons at the p < 0.05 level.

(a) Data are from public and most private hospitals. Excludes private hospitals in the Northern Territory.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification in Health 2010). Causes of injury are based on the first reported external cause as 'assault' ICD–10–AM codes X85–Y09, where the principal diagnosis was 'injury and poisoning' (S00–T98).

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised and are for New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland only. These six jurisdictions are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(e) Age-specific rate per 1,000 population.

(f) LCL = lower confidence limit.

(g) UCL = upper confidence limit.

(h) Rate ratio Indigenous: non-Indigenous.

(i) Rate difference Indigenous minus non-Indigenous Australians.

(j) Directly age-standardised rates using the Australian 2001 standard population.

Note: Population estimates are based on the 2006 Census.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by state/territory

Table 2.10.17 presents hospitalisations for a principal diagnosis of injury and poisoning and a first reported external cause of assault for the 2-year period July 2008 to June 2010 for New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Rates for Tasmania, the Australian Capital Territory have also been included however should be interpreted with caution.

- Over the period July 2008 to June 2010, Indigenous hospitalisation rates for assault ranged from 4.2 per 1,000 in Victoria to 21.7 per 1,000 in the Northern Territory.
- Indigenous Australians were hospitalised for assault at more than 15 times the rate of non-Indigenous Australians in Western Australia, South Australia and the Northern Territory. In New South Wales, Victoria and Queensland, rate ratios were between 5 and 7.
- The highest rate difference of hospitalisation for assault between Indigenous and non-Indigenous Australians, which was 20.3 per 1,000 population, occurred in the Northern Territory, followed by Western Australia (17.9 per 1,000) and South Australia (15.8 per 1,000).

Hospitalisation rates by state/territory should be interpreted with caution due jurisdictional differences in the level of Indigenous under-identification in hospital separations data.

Table 2.10.17: Hospitalisations with a principal diagnosis of injury and poisoning and a first reported external cause of assault, by Indigenous status and jurisdiction, July 2008 to June 2010 (a)(b)(c)(d)(e)

Hospitalisations by remoteness

Hospitalisation with a principal diagnosis of injury and poisoning and a first reported external cause of assault in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined are presented by Australian Standard Geographical Classification (ASGC) in Table 2.10.18.

- During the period July 2008 to June 2010, Indigenous Australians across all remoteness categories were more likely to be hospitalised for assault than non-Indigenous Australians.
- Hospitalisation rates for assault were highest for Indigenous people living in *Remote* areas, at 24.6 per 1,000 and lowest in *Major cities* (4.6 per 1,000). The same pattern was evident for non-Indigenous Australians.
- The greatest rate ratio between Indigenous and non-Indigenous hospitalisation rates for assault were in *Remote* areas of Australia, where Indigenous people were hospitalised at more than 16 times that of non-Indigenous Australians. Inner regional areas had the lowest rate ratio, with Indigenous persons hospitalised for assault at 5.4 times the rate of non-Indigenous Australians. Nationally the rate ratio was 12.2.
- Remote areas had the greatest rate difference between Indigenous and non-Indigenous hospitalisation rates for assault (23.1 per 1,000).

Table 2.10.18: Hospitalisations with a principal diagnosis of injury and poisoning and a first reported external cause of assault, by Indigenous status and remoteness, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010(a)(b)(c)(d)(e)(f)

* Indicates a significant difference at the p <0.05 level.

(a) Data are from public and most private hospitals. Data exclude private hospitals in the Northern Territory.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification in Health 2010). Causes of injury are based on the first reported external cause as 'assault' ICD–10–AM codes X85–Y09, where the principal diagnosis was 'injury and poisoning' (S00–T98).

(c) Financial year reporting.

(d) Data are reported by state/territory and remoteness of usual residence of the patient hospitalised.

(e) Directly age-standardised using the Australian 2001 standard population, by 5 year age groups to 65+

(f) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(g) LCL = lower confidence limit.

(h) UCL = upper confidence limit.

(i) Rate ratio Indigenous: non-Indigenous Australians.

(j) Rate difference Indigenous- non-Indigenous.

(k) Includes remote Victoria.

(l) Excludes remote Victoria.

(m) Total includes hospitalisations where ASGC is missing.

Notes

1. Rates are calculated using the remoteness distribution by Indigenous status, age and sex based on the 2006 ERP and applied to the 2008–10 population projections (Series B) based on the 2006 Census.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Time series analyses

Time series data are presented for the four jurisdictions that have been assessed as having adequate identification of Indigenous hospitalisations for all years from 1998–99 to 2009–10—Queensland, Western Australia, South Australia and the Northern Territory. These four jurisdictions represent approximately 60% of the Indigenous Australian population. New South Wales and Victoria were identified as having adequate identification of Indigenous hospitalisations from 2004–05 onwards; therefore, they were included as part of the current period analysis (2008–10) but not as part of the time series analyses.

Hospitalisation rates, rate ratios and rate differences between Indigenous and non-Indigenous Australians for assault over the 12-year period 1998–99 to 2009–10 are presented in Table 2.10.19 and Figure 2.10.1.

- Over the period 1998–99 to 2009–10, there were no significant changes in the hospitalisation rates for assault among Indigenous males and females.
- Over the same period there were significant increases in the hospitalisation rates for assault for non-Indigenous Australians (increase of 22%).
- There was a significant decline in the hospitalisation rate ratios between Indigenous and non-Indigenous Australians for assault over the period 1998–99 to 2009–10, and no significant change in the rate differences.

Note that changes in the level of accuracy of Indigenous identification in hospital records will result in changes in the level of reported hospital separations for Indigenous Australians. Also, changes in access, hospital policies and practices all affect the level of hospitalisation over time. Caution should be used in interpreting changes over time as it is not possible to ascertain whether a change in reported hospitalisation is due to changes in the accuracy of Indigenous identification or real changes in the rate at which Indigenous people are hospitalised. An increase in hospitalisations may reflect better access rather than a worsening of health.

Table 2.10.19: Age-standardised hospitalisation rates, rate ratios and rate differences between Indigenous and non-Indigenous Australians for a principal diagnosis of injury and poisoning and a first reported external cause of assault, Qld, WA, SA and NT, 1998–99 to 2009–10 [(a)]

Figure 2.10.1: Hospitalisation rates, rate ratios and rate differences between Indigenous and non-Indigenous Australians for a principal diagnosis of injury and poisoning and a first reported external cause of assault, Qld, WA, SA and NT, 1998-1999 to 2009-2010

Mortality

Table 2.10.20 and 2.10.21 present deaths from assault in New South Wales, Queensland, Western Australia, South Australia and the Northern Territory over the 5-year period 2006–2010.

- Over the period 2006–2010, there were 178 deaths of Indigenous people from assault (homicide) in New South Wales, Queensland, Western Australia, South Australia and the Northern Territory combined (Table 2.10.20). This represented approximately 1.6% of total deaths of Aboriginal and Torres Strait Islander people in these states and territories.
- The mortality rate from assault was 8.6 per 100,000 population for Indigenous Australians, compared to 1.0 per 100,000 population for non-Indigenous Australians. Indigenous Australians in the five states and territories combined died from assault at 8.9 times the rate of non-Indigenous Australians.

Mortality by age and sex

- Mortality rates for assault was highest for Indigenous persons aged 35–44 (19 per 100,000 population), followed by 25–34 and 45–54 (13 per 100,000). For non-Indigenous persons, mortality rates for assault were highest amongst those aged 25–34 and 35–44 (1.4 per 100,000), followed by 45–54 (1.1 per 100,000). In these age groups, Indigenous Australians died from assault at between 9.6 and 13.6 times the rate of non-Indigenous Australians (Table 2.10.20; Figure 2.10.2).
- For both Indigenous and non-Indigenous Australians, the mortality rate for assault among males was higher than among females. Indigenous males and females died from assault at around 8 and 11 times the rate of non-Indigenous males and females respectively (Table 2.10.21).

Table 2.10.20: Deaths from assault (homicide), by Indigenous status and age, NSW, Qld, WA, SA and NT, 2006–2010[(a)(b)(c)(d)(e)]

Total (age standardised)[(k)]	**178**	**8.6**	**7.2**	**9.9**	**718**	**1.0**	**0.9**	**1.0**	**8.9***	**7.6***

* Represents results with statistically significant differences at the p<0.05 level in the Indigenous/non-Indigenous comparisons at the p < 0.05 level.

(a) Data are reported for New South Wales, Queensland, Western Australia, South Australia and the Northern Territory only. These five states and territories are currently considered to have adequate levels of Indigenous identification in mortality data for these periods. Data for these five jurisdictions over-represent Indigenous populations in less urbanised and more remote locations. Mortality data for the five jurisdictions should not be assumed to represent the experience in the other jurisdictions.

(b) Although most deaths of Indigenous Australians are registered, it is likely that some are not accurately identified as Indigenous. Therefore, these statistics are likely to underestimate the Indigenous mortality rate. It is also difficult to exactly identify the difference between the Indigenous and non-Indigenous mortality rates because of these data quality issues.

(c) Deaths prior to 2007 are by year of registration and state/territory of usual residence. Deaths from 2007 onwards are by reference year and state/territory of usual residence. Registration year prior to 2007 is equivalent to reference year from 2007 onwards.

(d) Care should be taken when interpreting mortality rates for Queensland due to recent changes in the timeliness of birth and death registrations. Queensland deaths data for 2010 have been adjusted to minimise the impact of late registration of deaths on mortality indicators.

(e) All causes of death data from 2007 onward are subject to a revisions process - once data for a reference year are 'final', they are no longer revised. Affected data in this table are: 2007 (final), 2008 (final), 2009 (revised) and 2010 (preliminary). See Causes of Death, Australia, 2010 (cat.no. 3303.0) Explanatory Notes for further information.

(f) Age-specific death rates for age groups calculated per 100,000 estimated resident population for selected age group.

(g) LCL = lower confidence limit.

(h) UCL = upper confidence limit.

(i) Rate ratio is the mortality rate for Indigenous Australians divided by the mortality rate for non-Indigenous Australians.

(j) Rate difference is the mortality rate for Indigenous Australians minus the mortality rate for non-Indigenous Australians.

(k) Rates are directly age-standardised death rates per 100,000, using the 2001 Australian Estimated Resident population, by 5-year age group to 75+.

Notes

1. ICD–10 codes X85–Y09.
2. Deaths with not stated age have been excluded from the calculation of rates, but included in totals. Note that the ABS pro ratas not stated age across each age group in the calculation of mortality rates. This leads to some small differences in the mortality rates as calculated by ABS and AIHW.

Source: AIHW analysis of ABS Mortality Database.

Figure 2.10.2: Age-specific mortality rates for assault (homicide), by Indigenous status and age, NSW, Qld, WA, SA and NT, 2006–2010

Mortality by state/territory

- During 2006–2010, in the Northern Territory, the age standardised mortality rate from assault among Indigenous Australians was 18 per 100,000, while in New South Wales, the rate was 3.8 per 100,000 (Table 2.10.22).
- The highest rate ratio of mortality from assault occurred in Western Australia, where Indigenous Australians died from assault at about 16 times the rate for non-Indigenous Australians. New South Wales had the lowest rate ratio, which was 3.8. Nationally, the rate ratio was 8.9. The highest rate difference (16.2 per 100,000) occurred in the Northern Territory. Nationally, the rate difference was 7.6 per 100,000 population.

Time series analyses

Longer term mortality trend data are limited to three jurisdictions—Western Australia, South Australia and the Northern Territory for 1991 onwards, and five jurisdictions —New South Wales, Queensland, Western Australia, South Australia and the Northern Territory for 1998 onwards. These jurisdictions have over 10 years of reasonable coverage of Indigenous deaths in their recording systems.

There is a consistent time series of population estimates from 1991. Because of changes in the classification and coding of causes of death from ICD–9 (used up until 1996) to ICD–10 (used from 1997 onwards) which affect the comparability of the data, the analysis reported for this indicator has been undertaken for two time periods—1991–1996 and 1997–2010. Data are presented in 3-year or 4-year groupings because of low numbers of deaths from assault each year.

Because of the late inclusion of a 'not stated' category of Indigenous status in 1998 (before which 'not stated' responses were included with non-Indigenous deaths), Indigenous mortality rates have been compared with the mortality rates of other Australians (which include deaths of both non-Indigenous people and deaths for which Indigenous status was not stated).

Mortality rates, rate ratios and rate differences between Indigenous and other Australians for assault over the periods 1991–1993 to 1994–1996 and 1997–1999 to 2009–2010 are presented in Table 2.10.23 and Figure 2.10.3. Mortality rates, rate ratios and rate differences between Indigenous and other Australians for assault over the period 2001–2002 to 2009–2010 are presented in Table 2.10.24 and Figure 2.10.4.

- For the two time periods 1991–1993 and 1994–1996, the mortality rate from assault for Indigenous Australians in Western Australia, South Australia and the Northern Territory combined was 25.0 and 18.6 per 100,000 respectively. For other Australians, the mortality rate for assault was 1.5 per 100,000 in 1991–1993 and 1.7 per 100,000 in 1994–1996 (Table 2.10.23).
- Over the period 1997–1999 to 2009–2010, there was a non-significant increase in the mortality rates from assault for Indigenous Australians and a non-significant decline in mortality rates from assault for other Australians (Table 2.10.23).

Fluctuations in the level of Indigenous mortality over time partly reflect changing levels of coverage of Indigenous deaths and population estimates. Given the volatility in the measures of Indigenous mortality, caution should be exercised in assessing trends in Indigenous mortality over time and comparisons between jurisdictions and with the non-Indigenous population.

Table 2.10.23: Age-standardised mortality rates, rate ratios and rate differences for deaths from assault (homicide), WA, SA and NT, 1991–1993 to 1994–1996 and 1997–1999 to 2009–2010(a)(b)(c)(d)

(continued)

Table 2.10.23 (continued): Age-standardised mortality rates, rate ratios and rate differences for deaths from assault (homicide), WA, SA and NT, 1991–1993 to 1994–1996 and 1997–1999 to 2009–2010[a][b][c][d]

* Represents statistically significant differences at the $p < 0.05$ level over the periods 1991–1993 to 1994–1996 and 1997–1999 to 2009–2010.

(a) Data are reported for Western Australia, South Australia and the Northern Territory only. These three jurisdictions are considered to have adequate levels of Indigenous identification in mortality data for the time periods shown. They do not represent a quasi-Australian figure.

(b) Although most deaths of Indigenous Australians are registered, it is likely that some are not accurately identified as Indigenous. Therefore, these statistics are likely to underestimate the Indigenous mortality rate. It is also difficult to exactly identify the difference between the Indigenous and other mortality rates because of these data quality issues.

(c) Deaths prior to 2007 are by year of registration and state/territory of usual residence. Deaths from 2007 onwards are by reference year and state/territory of usual residence. Registration year prior to 2007 is equivalent to reference year from 2007 onwards.

(d) All causes of death data from 2007 onward are subject to a revisions process - once data for a reference year are 'final', they are no longer revised. Affected data in this table are: 2007 (final), 2008 (final), 2009 (revised) and 2010 (preliminary). See Causes of Death, Australia, 2010 (cat.no. 3303.0) Explanatory Notes for further information.

(e) Other includes non-Indigenous and Indigenous not stated.

(f) Rates are directly age-standardised death rates per 100,000, using the 2001 Australian Estimated Resident population, by 5-year age group to 75+.

(g) LCL = lower confidence limit.

(h) UCL = upper confidence limit.

(i) Rate ratio is the mortality rate for Indigenous Australians divided by the mortality rate for other Australians.

(j) Rate difference is the mortality rate for Indigenous Australians minus the mortality rate for other Australians.

(k) Mortality rate for 1994–1996 minus mortality rate for 1991–1993.

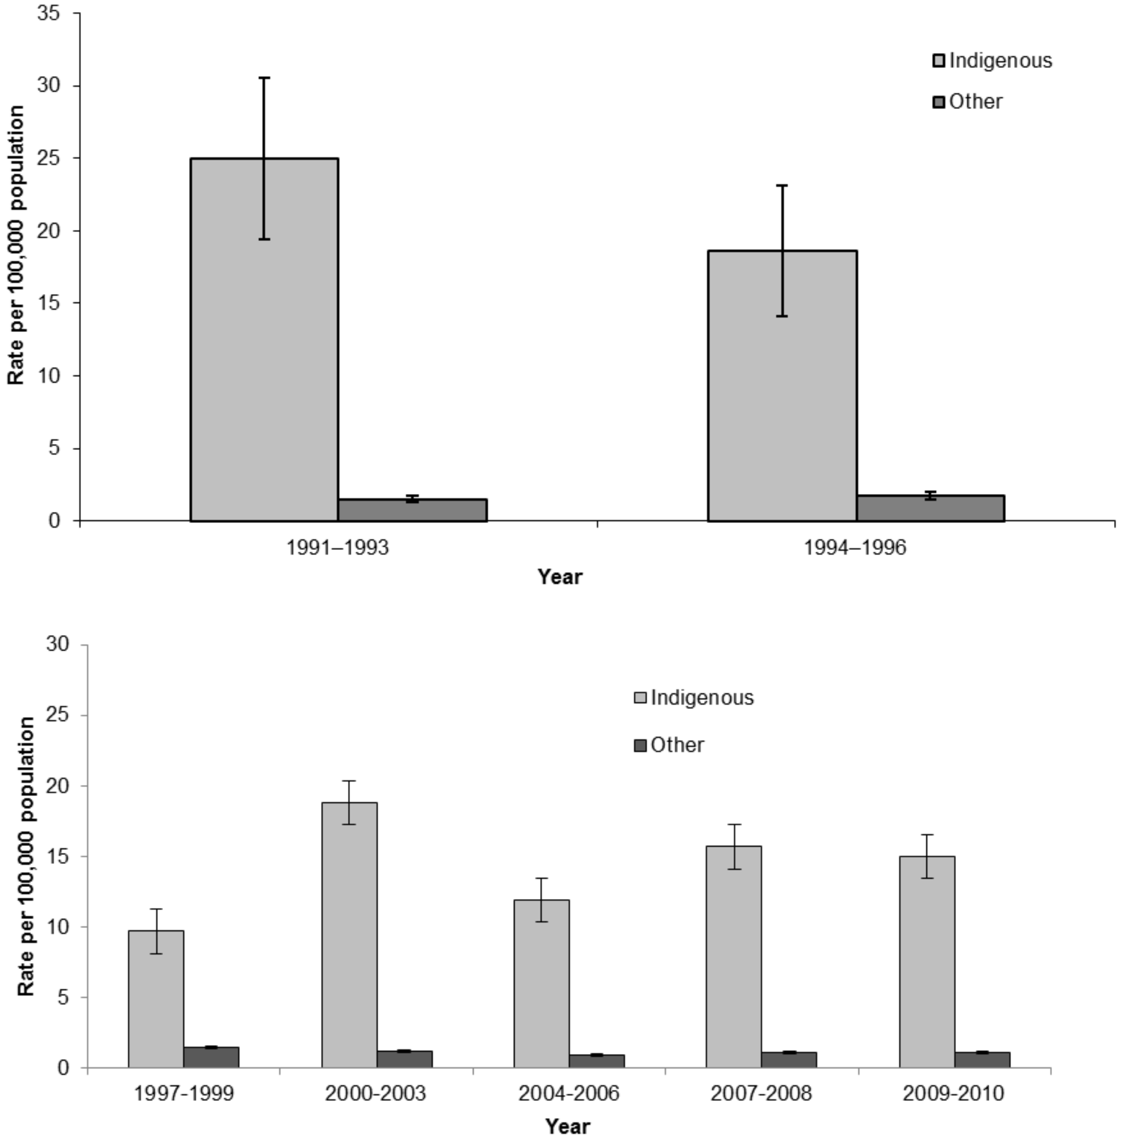
(l) Average annual change in rates, rate ratios and rate differences determined using linear regression analysis over the periods 1997–2010.

(m) Per cent change between 1997 and 2010 based on the average annual change over the period.

Notes

1. 1991–1996 ICD9 codes E960–E969, 1997–2010 ICD–10 codes X85–Y09.
2. Deaths with not stated age have been excluded from the calculation of rates, but included in totals. Note that the ABS pro ratas not stated age across each age group in the calculation of mortality rates. This leads to some small differences in the mortality rates as calculated by ABS and AIHW.

Source: AIHW analysis of ABS Mortality Database.



Source: ABS and AIHW analysis of ABS Mortality Database

Figure 2.10.3: Age-standardised mortality rates from assault (homicide), by Indigenous status, 1991–1993 to 1994–1996 and 1997–1999 to 2009–2010

Additional trends analysis has been presented for New South Wales, Queensland, Western Australia, South Australia and the Northern Territory combined from 2001–2002 to 2009–2010 for Indigenous and non-Indigenous Australians in Table 2.10.24 and Figure 2.10.5. Data are presented in 2-year groupings because of low numbers of deaths from assault each year. Queensland has had adequate identification of Indigenous deaths in its recording systems since 1998, and these have been compared with those of non-Indigenous Australians (excluding deaths for which Indigenous status was not stated).

- Over the period 2001–2002 to 2009–2010 in New South Wales, Queensland, Western Australia, South Australia and the Northern Territory combined, there was a non-significant decline in mortality rates from assault for Indigenous Australians; and a significant decline for non-Indigenous Australians (Table 2.10.24).
- There was no significant change in the mortality rate ratio or rate difference between Indigenous and non-Indigenous Australians over the period 2001 to 2010 (Table 2.10.24).

Table 2.10.24: Age-standardised mortality rates, rate ratios and rate differences for deaths from assault (homicide), NSW, Qld, WA, SA and NT, 2001–2010(a)(b)(c)(d)(e)(f)

	2001–2002	2003–2004	2005–2006	2007–2008	2009–2010	Annual change(g)	Per cent change(h)
Indigenous deaths per 100,000(i)							
Males	11.4	9.6	10.8	9.8	9.5	–0.2	–13.6
Females	8.8	4.2	5.9	8.7	5.7	–0.1	–7.9
Persons	10.0	6.9	8.3	9.2	7.6	–0.1	–11.6
Non-Indigenous deaths per 100,000(j)							
Males	1.7	1.4	1.2	1.3	1.2	–0.05*	–25.9*

Rate difference(l)							
Males	9.7	8.3	9.6	8.6	8.3	–0.1	–11.5
Females	7.8	3.6	5.3	8.0	5.1	0.0	–5.4
Persons	8.7	5.9	7.3	8.2	6.7	–0.1	–9.2

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 2001–2002 to 2009–2010.

(a) Data are reported for New South Wales, Queensland, Western Australia, Western Australia, South Australia and the Northern Territory only. These five states and territories are considered to have adequate levels of Indigenous identification in mortality data. Data for these five jurisdictions over-represent Indigenous populations in less urbanised and more remote locations. Mortality data for the five jurisdictions should not be assumed to represent the experience in the other jurisdictions.

(b) Although most deaths of Indigenous Australians are registered, it is likely that some are not accurately identified as Indigenous. Therefore, these statistics are likely to underestimate the Indigenous mortality rate. It is also difficult to exactly identify the difference between the Indigenous and non-Indigenous mortality rates because of these data quality issues.

(c) Data are presented in 2-year groupings because of small numbers each year.

(d) Deaths prior to 2007 are by year of registration and state/territory of usual residence. Deaths from 2007 onwards are by reference year and state/territory of usual residence. Registration year prior to 2007 is equivalent to reference year from 2007 onwards.

(e) Care should be taken when interpreting mortality rates for Queensland due to recent changes in the timeliness of birth and death registrations. Queensland deaths data for 2010 have been adjusted to minimise the impact of late registration of deaths on mortality indicators.

(f) All causes of death data from 2007 onward are subject to a revisions process - once data for a reference year are 'final', they are no longer revised. Affected data in this table are: 2007 (final), 2008 (final), 2009 (revised) and 2010 (preliminary). See Causes of Death, Australia, 2010 (cat.no. 3303.0) Explanatory Notes for further information.

(g) Average annual change in rates, rate ratios and rate differences determined using linear regression analysis over the periods 2001–2010.

(h) Per cent change between 2001 and 2010 based on the average annual change over the period.

(i) Rates are directly age-standardised death rates per 100,000, using the 2001 Australian Estimated Resident population, by 5-year age group to 75+.

(j) Rate ratio is the mortality rate for Indigenous Australians divided by the mortality rate for non-Indigenous Australians.

(k) Rate difference is the mortality rate for Indigenous Australians minus the mortality rate for non-Indigenous Australians.

Notes

1. ICD–10 codes X85–Y09.
2. Deaths with not stated age have been excluded from the calculation of rates, but included in totals. Note that the ABS pro ratas not stated age across each age group in the calculation of mortality rates. This leads to some small differences in the mortality rates as calculated by ABS and AIHW.

Figure 2.10.4: Mortality rates, rate ratios and rate differences for deaths from assault (homicide) between Indigenous and non-Indigenous Australians, NSW, Qld, WA, SA and NT, 2001–2002 to 2009–2010

Victims of homicide

The National Homicide Monitoring Program collects data on all homicides recorded in Australia. Table 2.10.25 presents data from 1998 to 2010 as four periods of 3-financial years.

- In general, over the four 3-year periods from 1998–99 to 2000–01 until 2007–08 to 2009–10, the number of deaths from homicide decreased for Indigenous Australians (from 134 in 1998–99 to 2000–01, to 99 in 2007–08 to 2009–10) and non-Indigenous Australians (from 864 in 1998–99 to 2000–01, to 686 in 2007–08 to 2009–10) (Table 1.10.25).
- In 2007–08 to 2009–10, 12% of persons who died from homicide were Indigenous Australians. This was the lowest over the four periods. The highest occurred in in 2004–05 to 2006–07 at 14%.
- Most of the deaths from homicide were caused by male offenders (about 80% for Indigenous and 90% for non-Indigenous).
- For Indigenous Australians, in most of cases of homicide, both the offender and the victim were not working (unemployed/not in the labour force), ranging from 76% in 2007–08 to 2009–10, to 88% in 2004–05 to 2006–07. For non-Indigenous Australians, the proportions ranged from 39% in 2007–08 to 2009–10, to 47% in 1998–99 to 2001–02.
- For both Indigenous and non-Indigenous Australians, most of the homicides happened between intimate partners, family members, friends and acquaintances (around 90% for Indigenous and 80% for non-Indigenous).

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: Users' guide, 2008* (ABS 2010).

Community safety and family violence data

The sensitive nature of many of the issues surrounding community safety could also influence responses to these questions. Any data that are self-reported are likely to underestimate circumstances in which the respondent may feel frightened or ashamed or be unwilling to admit to the data collector, such as experience of family violence involvement with the police. Any such self-reported figures are likely to underestimate the occurrence of the circumstance in question.

In addition, the NATSISS question on 'family violence' does not directly measure experience of family violence, because it asks about whether certain issues are a problem in the neighbourhood/community. However, these data do provide useful information about the social setting for family violence.

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and ACT data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only (AIHW 2010).

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

Mortality data

Mortality data presented in this report are from the AIHW National Mortality Database. The AIHW National Mortality Database includes information on the factors that caused death, as well as other information about the deceased person, such as age at death, place of death, country of birth, and where applicable, the circumstances of their death. These data are collected in Australia by the Registrars of Births, Deaths and Marriages in each state and territory. The data are then compiled nationally by the ABS, which codes the data according to the International Classification of Diseases (ICD).

Deaths

Although it is considered likely that most deaths of Aboriginal and Torres Strait Islander (Indigenous) Australians are registered, a proportion of these deaths are not registered as Indigenous. Information about the deceased is supplied by a relative or other person acquainted with the deceased, or by an official of the institution where the death occurred and may differ from the self-identified Indigenous origin of the deceased.

Qld deaths

In November 2010, the Queensland Registrar of Births, Deaths and Marriages advised the ABS of an outstanding deaths registration initiative undertaken by the Registry. This initiative resulted in the November 2010 registration of 374 previously unregistered deaths which occurred between 1992 and 2006 (including a few for which a date of death was unknown). Of these, around three-quarters (284) were deaths of Aboriginal and Torres Strait Islander Australians.

The ABS discussed different methods of adjustment of Queensland death registrations data for 2010 with key stakeholders. Following the discussion, a decision was made by the ABS and key stakeholders to use an adjustment method that added together deaths registered in 2010 for usual residents of Queensland which occurred in 2007, 2008, 2009 and 2010. This method minimises the impact on mortality indicators used in various government reports. However, care should still be taken when interpreting Aboriginal and Torres Strait Islander death data for Queensland for 2010**.**

Western Australia deaths

Indigenous deaths registered in Western Australia in 2007, 2008 and 2009 were corrected by the ABS in mid-2012 due to some non-Indigenous deaths being incorrectly recorded as Indigenous for these years. Data presented in this report are based on the corrected data and will differ from mortality data presented in the 2010 Health Performance Framework report which presented data prior to the ABS corrections.

Indigenous status question

All jurisdictions comply with the standard wording for the Indigenous status question and categories for their death registration forms.

Under-identification

At present, there is considerable variation across the states and territories in the completeness of mortality data for Indigenous people. Information concerning the number of deaths of Indigenous people is limited by the accuracy with which Indigenous persons are identified in death records. Problems associated with identification result in an underestimation of deaths of Indigenous people and in the gap in mortality between Indigenous and non-Indigenous Australians.

Mortality data for New South Wales, Queensland, Western Australia, South Australia and the Northern Territory are considered to have sufficient coverage to produce reliable statistics on Indigenous Australian deaths for the period 2001–2010.

Longer term mortality trend data are limited to three jurisdictions (Western Australia, South Australia and the Northern Territory) which are considered to have adequate identification from 1991. Queensland is considered to have sufficient coverage of Indigenous deaths from 1998.

The quality of the time series data is also influenced by the late inclusion of a 'not stated' category for Indigenous status in 1998. Before this time, the 'not stated' responses were probably included with the non-Indigenous.

Note that different causes may have levels of under-identification that differ from the all-cause coverage estimates. Note also that the quality of the cause of death data depends on every step of the process of recording and registering deaths (including the documentation available at each step of the process) from certification to coding of cause of death.

Indigenous Mortality Quality Study

The ABS conducted a number of quality studies based on the 2006 Census of Population and Housing and other data sets as part of the Census Data Enhancement (CDE) project (ABS 2008). The CDE Indigenous Mortality Quality Study linked Census records with death registration records for the 11-month period following the Census and examined differences in the reporting of Indigenous status across the two data sets.

For the purpose of this study, the linked record was assumed to be an Indigenous record if a positive response was recorded against the Indigenous status question on either the death registration or the corresponding Census record. Following linkage, the number of death records identified as Indigenous increased from 1,800 to 2,123 records, or from 1.7% to 2.0% of all registered deaths.

'While 323 additional death records were able to be identified as Indigenous from Census records, more may have been expected if all death records had been linked. A key reason records could not be linked appears to be Census undercount, with a corresponding Census record not existing to link to for many Indigenous death records' (ABS 2008).

The results from the study suggested that coverage of Indigenous deaths in death registrations is considerably higher, at least in 2006–07, than previous estimates have indicated. Nationally, the coverage rate was estimated to be 85%. State/territory coverage estimates were: New South Wales 76%, Victoria 74%, Queensland 87%, South Australia 86%, Western Australia 92% and Northern Territory 99% (ABS 2008).

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in death records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used here are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

National Homicide Monitoring Program (NHMP)

The NHMP was established in 1990 and reports annually by financial year on all homicides recorded in Australia. The Indigenous status of the victim is based on police identification of 'racial appearance', and therefore will underestimate the level of homicide involving Indigenous persons. Nevertheless, the NHMP includes useful information on the circumstances surrounding homicides involving Indigenous persons.

List of tables

List of figures

2.11 Contact with criminal justice system

The prevalence of Aboriginal and Torres Strait Islander people in prison custody, other contact with the criminal justice system, including police custody and juvenile justice, and relationships with health and social factors.

Data sources

Data for this measure come from the National Prison Census, the National Deaths in Custody Program annual report, the Drug Use Monitoring in Australia survey and the National Aboriginal and Torres Strait Islander Social Survey, the Juvenile Justice National Minimum Data Set and the National Prisoner Health Census.

National Prisoner Census

The ABS collects data from administrative records on persons in prison custody on 30 June each year in all jurisdictions. This Census includes all prisoners in adult corrective services, but not persons in juvenile institutions, psychiatric care or police. The Census collects information on the number of people in custody, legal status (sentenced or unsentenced), prior imprisonment, the most serious offence committed and length of sentence.

Most jurisdictions collect Indigenous status from individual prisoners. It is uncommon for corrective services agencies to collect Indigenous status from anyone other than the prisoners themselves. However, the accuracy of these data has not been assessed.

Deaths in Custody Australia

As a requirement of the Deaths in Custody Royal Commission, the Australian Institute of Criminology (AIC) collects data on deaths in custody each year for all jurisdictions. Data collected include custodial authority (police, prison, juvenile justice/welfare), legal status (sentenced or unsentenced), cause of death, manner of death, location of death and most serious offence.

Indigenous status is determined by previous self-identification to prison authorities.

Drug Use Monitoring in Australia (DUMA) Survey

DUMA is an annual survey which has been conducted by the AIC since 1999 at some locations across Australia. The survey reports on drug use among police detainees at selected police stations. The survey is by a voluntary questionnaire and drug use is confirmed by a urine sample provided by the detainee.

The number of detainees questioned is quite low and thus includes a very small Indigenous sample. The Indigenous status of the detainee is established by the following question: ‘What is your ethnic background?’ (if the respondent mentions ‘Australian’ but not ‘Aboriginal’, prompt: ‘Do you consider yourself an Aboriginal or Torres Strait Islander?’).

Analysis is presented by state/territory, as the figures do not permit national coverage.

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Juvenile Justice National Minimum Data Set

The Juvenile Justice National Minimum Data Set is held by the AIHW and contains data on young people under juvenile justice supervision in the community and in detention. These data are collected by the AIHW from the departments in each state and territory with responsibility for juvenile justice.

The JJ NMDS was initially developed between 2002 and 2004 and the first report containing data from the JJ NMDS was published in 2006. This first version of the JJ NMDS, contained information on only the most serious supervised legal arrangement or order for each young person under juvenile justice supervision. In 2009, the JJ NMDS was redeveloped to capture all supervised legal arrangements and orders for young people under juvenile justice supervision, rather than only the most serious one. This version of the JJ NMDS (known as JJ NMDS 2009) allows for a more complete analysis of the numbers and types of supervised orders that juvenile justice agencies administer.

National Prisoner Health Census

In 2010 the AIHW conducted the second National Prisoner Health Census. This census collected information from prisoners during a two week period in all states and territories except New South Wales and Victoria. It includes information on the health of prisoners at the time of entry to prisons, their use of health services while in prison, as well as some information on the prison environment. The Census data was used in compiling a report on indicators of the health of prisoners.

Most jurisdictions collect Indigenous status information from individual prisoners. It is uncommon for corrective services agencies to collect Indigenous status from anyone other than the prisoner themselves. The accuracy of this data has not been assessed.

Data analyses

People in prison custody

Data on Indigenous people in prison custody come from the ABS National Prison Census which collected information about persons held in Australian prisons on the night of 30 June 2011. These data are published in the ABS publication *Prisoners in Australia 2011* (ABS 2011).

- As at 30 June 2011, there were 7,655 Indigenous prisoners (7,639 aged 18 years and over) recorded in the National Prison Census (Table 2.11.1).
- After adjusting for differences in age structure, the age-standardised rate of imprisonment for Indigenous persons was 1,868 per 100,000 adult population compared with 130 per 100,000 adult population for non-Indigenous prisoners, making Indigenous people 14 times more likely than non-Indigenous persons to be in prison at 30 June 2009 (Table 2.11.2).
- Indigenous Australians were imprisoned at a crude rate of 2,248 per 100,000 (Table 2.11.2).

People in prison custody by age and sex

- The median age of Indigenous prisoners was 32 years compared with 37 years for non-Indigenous prisoners (Table 2.11.1).
- Imprisonment rates were highest among those aged 25–29 and 20–24 in the Indigenous population and among those aged 25–29 and 30–34 in the non-Indigenous population.
- Approximately 92% of the total Indigenous prisoners were male, and 8% were female. Imprisonment rates were much higher for Indigenous males than Indigenous females (4228 per 100,000 compared with 358 per 100,000). The non-Indigenous proportions of prisoners are similar, 93% are male, 7% are female, however the crude rates are lower 237 and 16 per 100,000 respectively (Table 2.11.1).

People in prison custody by state/territory

- Western Australia and South Australia recorded the highest age-standardised ratios of Indigenous to non-Indigenous rates of imprisonment, with Indigenous persons being 18 and 17 times as likely to be in prison as non-Indigenous Australians in these jurisdictions respectively (Table 2.11.2).

.

People in prison custody by legal status and most serious offence/charge

- As at 30 June 2011, approximately 76% of Indigenous prisoners had a prior imprisonment under sentence, compared with 48% of non-Indigenous prisoners (Table 2.11.3).
- The most common offences for Indigenous prisoners were acts intended to cause injury and unlawful entry with intent, being the most serious offences for 32% and 15% or all Indigenous prisoners respectively.
- For non-Indigenous prisoners the most common offences were illicit drug offences and acts intended to cause injury, each accounting for 15% of all imprisonments. Illicit drug offences were recorded as the most serious offence for only 1.4% of Indigenous prisoners.
- Indigenous prisoners were also less likely than non-Indigenous prisoners to have homicide recorded as the most serious offence (6% compared with 11%).
- Indigenous Australians were taken into prison custody for acts intended to cause injury and unlawful entry with intent at rates of 749 and 320 per 100,000 adult population respectively (Figure 2.11.1).
- Non-Indigenous Australians were taken into prison custody for acts intended to cause injury and unlawful entry with intent at rates of 19 and 13 per 100,000 adult population respectively (Figure 2.11.2).

People in prison custody by sentence length

- As at 30 June 2011, the median sentence length for Indigenous sentenced prisoners was 24 months. The longest median sentence lengths were for homicide and related offences (120 months, or 10 years), sexual assault and related offences (84 months, or 7 years) and robbery, extortion and related offences (60 months, or 5 years) (Table 2.11.4).
- The mean (66 months) and median (47 months) sentence lengths for non-Indigenous sentenced prisoners was longer than those for Indigenous sentenced prisoners (44 months and 24 months, respectively) (ABS 2011).
- The mean (5.5 months) and median (3.2 months) time on remand for non-Indigenous unsentenced prisoners was longer than for Indigenous unsentenced prisoners (3.7 months and 2.0 months, respectively) (ABS 2011).

Time series analyses

Data on the imprisonment rates of Indigenous and non-Indigenous people aged 18 years and over are presented below for the period 2000–2011.

- During the period of 2000–2011 age-standardised Indigenous imprisonment rates increased steadily from 1,248 to 1,868 per 100,000. In comparison, the age-standardised imprisonment rates for non-Indigenous Australians remained relatively stable over this period (ranged from 123 per 100,000 in 2002 to 130 per 100,000 in 2011) (Figure 2.11.3; Table 2.11.5).
- The rate ratio of age-standardised imprisonment rates ranged from 9.6 in 2000 to 14.3 in 2009 (Figure 2.11.4; Table 2.11.5).

Deaths in custody

Data on deaths in custody in Australia come from the Australian Institute of Criminology (AIC) National Deaths in Custody Program and are presented below.

Deaths by selected characteristics

- In 2010–11, there were 21 Indigenous deaths in custody and 64 non-Indigenous deaths. In 2009–10 there was a similar number of Indigenous and non-Indigenous deaths (Tables 2.11.6a and 2.11.6b).
- In 2010–11, 57% of all Indigenous deaths in custody were within prison and 38% within police custody. This compares with 72% of non-Indigenous deaths in custody that were within prison and 28% within police custody (Table 2.11.6). In 2009–10, the proportion of Indigenous deaths within prison was 70% and police custody deaths was 30%; and the proportions of non-Indigenous deaths was 67% in prison and 33% in police custody (Table 2.11.7).
- In 2009–10, 95% of Indigenous deaths in custody were males, compared with 91%in 2010–11. Proportions for non-Indigenous male deaths were 98% in 2009–10 and 100% in 2010–11 (Tables 2.11.6 and 2.11.7).
- In 2009–10, New South Wales and Western Australia had the highest number of Indigenous deaths in custody (6 deaths in each state), while in 2010–11 Western Australia had the most deaths (7).
- In 2009–10 and 2010–11, natural causes were the most common causes of death for Indigenous and non-Indigenous people in custody.

- In both years, Indigenous deaths in custody were less likely than non-Indigenous deaths to be self-inflicted or to be caused by homicide. However, a higher proportion of Indigenous deaths were caused by accident.

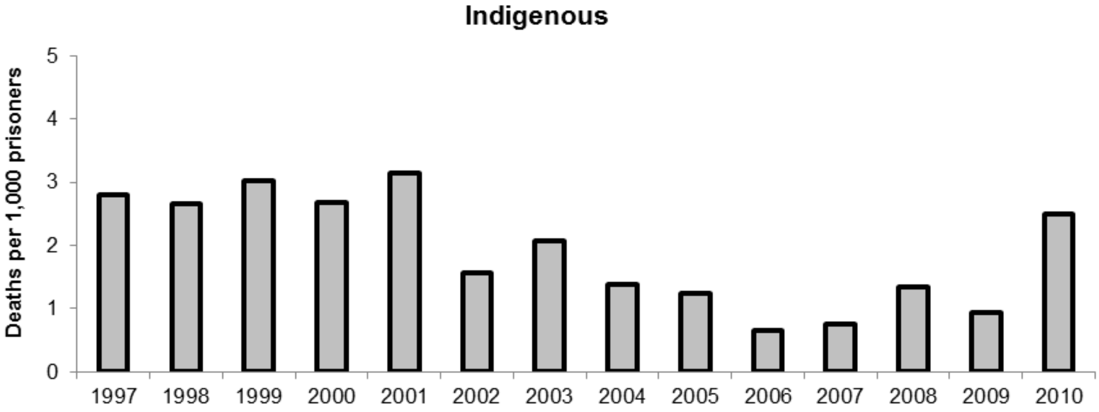
Time series analyses

Figures 2.11.5 and 2.11.6 and Table 2.11.8 present the crude death rates for Indigenous and other Australians in prison custody over the period 1997 to 2010.

- Over the period 1997 to 2010 there were between 3.1 and 0.7 Indigenous deaths in custody per 1,000 Indigenous prisoners (Figure 2.11.5).
- Over the same period, there were between 4.5 and 1.4 non-Indigenous deaths per 1,000 non-Indigenous prisoners (Figure 2.11.6).
- There has been a decline in the rates of deaths in prison custody for both Indigenous and non-Indigenous prisoners. Between 1997 and 2010 the average annual change in rates of Indigenous deaths decreased by 0.1 per 1,000 prisoners, while there was a 66% decrease in the per cent change over the whole period. This compares with non-Indigenous prisoners were the average annual change in rates decreased by 0.2, and the per cent change over the whole period decreased by 51% (Table 2.11.8).



Note: Rates are per 1,000 prison population and have not been age-standardised.

Detainees and drug use

The AIC Drug Use Monitoring in Australia (DUMA) survey reports on drug use among police detainees at selected police stations in Australia. The survey is by a voluntary questionnaire and drug use is confirmed by a urine sample provided by the detainee. Data from the 2010 and 2011 surveys are presented in Tables 2.11.9 and 2.11.10.

Data from 2010 DUMA survey

- In 2010, in all of the selected police stations shown in Table 2.11.9, there was a higher proportion of Indigenous detainees who tested positive to at least one drug than non-Indigenous detainees.
- Between 57% and 100% of Indigenous detainees at selected police stations in South Australia, New South Wales, Queensland, Western Australia, the Northern Territory and Victoria tested positive to drugs in 2010 compared with between 54% and 70% of non-Indigenous detainees.
- Cannabis was the most common drug for which both Indigenous and non-Indigenous detainees tested positive. Methamphetamines and benzodiazepines were also common drugs to which Indigenous and non-Indigenous detainees tested positive. Between 2.5%

and 55% of Indigenous detainees and between 2.3% and 29% of non-Indigenous detainees tested positive for multiple drugs.

Data from 2011 DUMA survey

Data from the 2011 DUMA survey is presented in table 2.11.10. Please note that this data only became available after the 2012 Aboriginal and Torres Strait Islander Health Performance Framework was published by the Department of Health and Ageing.

- In 2011, in all of the selected police stations shown in Table 2.11.9, there was a higher proportion of Indigenous detainees who tested positive to at least one drug than non-Indigenous detainees.
- Between 70% and 100% of Indigenous detainees at selected police stations in South Australia, New South Wales, Queensland, Western Australia, the Northern Territory and Victoria tested positive to drugs compared with between 52% and 71% of non-Indigenous detainees.
- Cannabis was the most common drug for which both Indigenous and non-Indigenous detainees tested positive. Methamphetamines and benzodiazepines were also common drugs to which Indigenous and non-Indigenous detainees tested positive. Between 4.4% and 40% of Indigenous detainees and between 2.1% and 24% of non-Indigenous detainees tested positive for multiple drugs.

Contact with police

Information on police contact with Indigenous persons is available from the 2008 NATSISS. This information is presented in tables 2.11.11 and 2.11.12. Table 2.11.11 compares the population characteristics of Indigenous people who were formally charged, or arrested or incarcerated in the last 5 years, with percentages being calculated within columns. Table 2.11.12 compares the police contact status of different elements of the Indigenous population, with percentages being calculated across the rows.

- In 2008, approximately 34% of Indigenous persons aged 15 years and over had been formally charged by the police, 15% had been arrested by the police in the previous 5 years and 36% had been incarcerated in the previous 5 years (Table 2.11.12).

Contact with police by selected characteristics

- Indigenous persons aged 35–44 years were most likely to have been formally charged, Indigenous persons aged 25–34 years were most likely to have been arrested by the police in the previous 5 years, and Indigenous persons aged 15–24 years were most likely to have been incarcerated by the police in the previous 5 years (Table 2.11.12).
- A higher proportion of Indigenous males than females had been formally charged (48% compared with 21%), arrested by police in the previous 5 years (22% compared with 9%) and incarcerated in the previous 5 years (37% compared with 30%) (Table 2.11.12).
- In 2008, Western Australian had the highest proportion of Indigenous people aged 15 years and over who had been formally charged (44%) (Table 2.11.12).
- Indigenous Australians with a disability or long-term health condition were more likely than those without a disability or long term health condition to have been formally charged, however they were almost as likely to be arrested in the last 5 years, and less likely to be incarcerated.
- Indigenous Australians aged 15 years and over who were current daily smokers, had consumed alcohol at moderate or high risk levels in the previous 12 months and had used substances in the previous 12 months were more likely to have been formally charged than Indigenous Australians who had not engaged in these activities (Table 2.11.12).
- In 2008, a higher proportion of Indigenous Australians in the lowest (1st) quintile of household income had been formally charged and arrested by the police in the previous 5 years than Indigenous Australians in the highest (5th) quintile of household income.
- The majority of Indigenous Australians who had been formally charged by police reported that the age at which they were first formally charged was between 12 and 24 years (78%) (Table 2.11.11).
- According to the 2008 NATSISS, 15% of Indigenous persons aged 15 years and over had been arrested in the previous 5 years, compared to 16% in 2002 and 23% in 2008. During 2008, 8% of Indigenous persons aged 15 years and over reported being arrested once and 7% reported being arrested more than once (ABS 2008).

Young people in unsentenced detention

Data on young people in unsentenced detention come from the AIHW Juvenile Justice National Minimum Data Set. Data on juvenile justice were first collected in 2000–01 and the data presented here are for 2009–10. These data exclude Western Australia and the Northern Territory, as data were not provided by these jurisdictions.

The term 'unsentenced detention' is used to indicate young people on remand (who have been remanded in custody by a court) and those under police referred detention (before an initial court appearance) (AIHW 2011a).

Young people in unsentenced detention by selected characteristics

- On an average day in 2009—10, 201 Indigenous and 232 non-Indigenous young people were in unsentenced detention (Table 2.11.13).
- For both Indigenous and non-Indigenous Australians, the majority of young people in unsentenced detention were in 14—17 year age group (Table 2.11.13).
- The rate of Indigenous Australians aged 10—17 years in unsentenced detention on an average day was 22 times the rate of non-Indigenous Australians (245 and 11 per 100,000, respectively) (Table 2.11.14).
- New South Wales (317 per 100,000) and South Australia (249 per 100,000) had the highest rates of Indigenous young people aged 10—17 years in unsentenced detention (Table 2.11.14).

Table 2.11.13: Number of young people in unsentenced detention on an average day, by age, Indigenous status and state/territory, 2009–10(a)

Total	**113**	**40**	**38**	**n.a.**	**20**	**14**	**8**	**n.a.**	**232**

(a) Number of young people on an average day may not sum to total due to rounding.

Notes

1. Western Australia and the Northern Territory did not supply JJ NMDS data for 2009–10.
2. Total includes young people with unknown age.
3. Age calculated as at start of financial year if first period of unsentenced detention in the relevant year began before the start of the financial year, otherwise age calculated as at start of first period of unsentenced detention in the relevant year.
4. Number of unsentenced and sentenced young people may not sum to total number of young people as some young people may have changed legal status during the same day.
5. People in the JJ NMDS who are aged 18 years or older include (a) young people who committed or allegedly committed an offence while aged 17 years or younger, who are supervised in relation to that offence when they are aged 18 years or older; and (b) people who were aged 18 years or older at the time of the offence who are supervised by the juvenile justice system rather than the adult correctional system because of their vulnerability or immaturity.

Source: AIHW 2011a. Juvenile justice in Australia 2009–10, table D23a.

Table 2.11.14: Rates of young people in unsentenced detention on an average day, by age, Indigenous status and state/territory, 2009–10(a)(b)

(a) Rates for Indigenous persons are calculated using population estimates based on the 2006 Census (Series B).

(b) Age calculated at start of financial year if period of detention began before start of financial year, otherwise age calculated as at start of period of detention.

(c) Australian Capital Territory single year of age population data not available for rate calculations.

(d) Rate ratio Indigenous: non-Indigenous.

(e) Rate difference: Indigenous minus non-Indigenous.

Notes

1. Western Australia and the Northern Territory did not supply JJ NMDS data for 2009–10.
2. Age calculated as at start of financial year if first period of unsentenced detention in the relevant year began before the start of the financial year, otherwise age calculated as at start of first period of unsentenced detention in the relevant year.

Source: AIHW analysis of Juvenile Justice National Minimum Data Set.

Completed periods of unsentenced detention

- In 2009—10, Indigenous young people completed periods of unsentenced detention that lasted a median length of 7 days, compared to 3 days for non-Indigenous young people (Table 2.11.15).
- Indigenous young people completed around 3,300 and non-Indigenous young people completed around 4,900 periods of unsentenced detention during 2009—10 (Table 2.11.15).
- The rate of Indigenous Australians aged 10—17 years who completed a period of unsentenced detention was 15 times the rate of non-Indigenous Australians (1,907 and 127 per 100,000, respectively) (Table 2.11.16).
- Of those aged 10—17 years who completed periods of unsentenced detention, around half of Indigenous people (51%) completed multiple periods, compared with 42% of non-Indigenous people (Table 2.11.16).

Table 2.11.15: Completed periods of unsentenced detention by Indigenous status and state/territory, 2009–10

Indigenous status	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	Aust. excl. WA & NT

Additional information

Prisoner health census

Selected data from the 2010 National Prisoner Health Census are presented in tables 2.11.17 to 2.11.25.

Further information is available from the AIHW's *The health of Australia's prisoners, 2010* (AIHW 2011b).

Health status of prisoners

- A similar proportion of Indigenous (78%) and non-Indigenous (74%) prison entrants consulted a medical professional for their own health in prison during the previous 12 months. The proportion of prison entrants who had consulted a medical professional for their own health in the community was 68% of Indigenous and 81% of non-Indigenous entrants (Table 2.11.17).
- During the previous 12 months, a similar percentage of Indigenous (10%) and non-Indigenous (13%) prison entrants needed to but did not consult with a medical professional while in prison. This compares with much higher proportions in the community (35% and 47% respectively) (Table 2.11.17).

Table 2.11.17: Access to medical advice(a) by Indigenous status and type of health service (community or prison), proportion of prison entrants(b) aged 18 years and over, 2010

	Indigenous	Non-Indigenous
	Per cent	
Consulted a medical professional for their own health in the community	68	81
Consulted a medical professional for their own health in prison	78	74
Needed to consult with a medical professional in the community but did not	35	47
Needed to consult with a medical professional while in prison but did not	10	13
Total number of prison entrants access to medical advice	**262**	**327**

(a) Consultations within the previous 12 months.

(b) Per cents are calculated from the total number of prison entrants (610) for the community visits, and from the number of Indigenous (135) and non-Indigenous (119) entrants reporting having been in prison during the previous 12 months for the prison visits.

Source: The health of Australia's prisoners, 2010 (AIHW 2011b).

- In 2010, 21% of prisons received visits at least every 2 weeks from an Aboriginal Community Controlled Health Organisation or an Aboriginal Medical Service (AIHW 2011b).
- A lower proportion of Indigenous (23%) than non-Indigenous (38%) prison entrants reported that they were told by a doctor, psychiatrist or psychologist that they have a mental health disorder (including alcohol and drug abuse). However, a higher proportion of Indigenous (73%) than non-Indigenous prison entrants (48%) reported a risk of alcohol-related harm, and a similar proportion reported they engaged in illicit drug use during the previous 12 months (68% and 65% respectively) (Table 2.11.18).

- The rates of diagnosed health conditions for Indigenous and non-Indigenous prison entrants were lower for asthma (13% and 27% respectively), and similar for cardiovascular disease (9% and 7% respectively) and diabetes (6% and 4% respectively) (Table 2.11.18).
- In 2010, similar proportions of Indigenous (39%) and non-Indigenous (40%) prisoners in custody used the prison clinic during the census period (AIHW 2011b).
- Similar proportions of Indigenous (4%) and non-Indigenous (3%) prisoners in custody who attended a clinic during the census period did so for a communicable disease. Note however, that this was the proportion of all prisoners who attended the clinic for a communicable disease, not the proportion of clinic visits for a communicable disease. It was from a two week snapshot of clinic attendance (and therefore is not related to prevalence data) and may be an underestimate because some prisoners may have attended the clinic for other conditions or symptoms arising from a communicable disease.

Table 2.11.18: Diagnosed health conditions, by Indigenous status and age, prison entrants aged 18 years and over, 2010

	Indigenous	Non-Indigenous
	Per cent	
Told by a doctor, psychiatrist or psychologist that they have a mental health disorder (including alcohol and drug abuse)	23	38
Told by a doctor or nurse that they have ever had asthma	13	27
Told by a doctor or nurse that they have ever had cardiovascular disease	9	7
Told by a doctor or nurse that they have ever had arthritis	5	13
Told by a doctor or nurse that they have ever had diabetes	6	4
Risk of alcohol related harm (self-report)	73	48
Report they have engaged in illicit drug use in the last 12 months	68	65
Total number of prison entrants	**262**	**327**
Attended clinic during census period due to communicable disease[(a)(b)(c)(d)]	4	3
Total number of prisoners in custody	**1,912**	**3,590**

(a) Attending clinic data is for prisoners in custody, not all prison entrants.

(b) Proportion of all prisoners who attended the clinic for a communicable disease. Not the proportion of clinic visits for a communicable disease.

(c) From a two week snapshot of clinic attendance (therefore not related to prevalence data).

(d) May be an underestimation because some prisoners may have attended the clinic for other conditions or symptoms arising from a communicable disease.

Source: The health of Australia's prisoners, 2010 (AIHW 2011b).

Education level

- Educational attainment among Indigenous prison entrants was lower than for the general Indigenous population; 9% of Indigenous prisoners aged 18–24 years had completed Year 12 or equivalent, compared with 33% of all Indigenous Australians in the same age group (Table 2.11.19).
- Across all age groups Indigenous prisoners were twice as likely as the general Indigenous population to have Year 9 or below as their highest level of school completed (Table 2.11.19).

Table 2.11.19: Indigenous prison entrants (2010) and the general Indigenous population (2008), by education status and age group (per cent)

	Indigenous prisoners (years)			General Indigenous population (years)		
	18–24	25–34	35–44	18–24	25–34	35–44
Highest year of school completed						
Year 12 or equivalent	9	8	18	33	30	27
Year 10 or 11	48	47	44	47	49	51
Year 9 or below	44	46	39	20	21	22
Non-school qualification						
Has a non-school qualification	19	18	14	25	36	42

Notes

1. Excludes New South Wales and Victoria, as they did not participate in the 2010 Prison Census.
2. Indigenous data were sourced from entrant forms, National Prisoner Health Census 2010.
3. General Indigenous population data was from AIHW analysis of 2008 National Aboriginal and Torres Strait Islander Social Survey.

Source*:* The health of Australia's prisoners, 2010 (AIHW 2011b).

Employment status

- In the 30 days prior to imprisonment, two-thirds (67%) of Indigenous prison entrants aged 18–24 years were unemployed, compared with 13% of those in the general Indigenous population of the same age. Just one-quarter (25%) of prison entrants aged 18–24 years were employed, making them the age group least likely to be employed prior to imprisonment (Table 2.11.20).
- The unemployment rate decreased with increasing age for Aboriginal and Torres Strait Islander people in both population groups, reducing from 67% of prison entrants aged 18–24 years to 40% of prison entrants aged 35–44 years, and 13% of those in the general Indigenous population aged 18–24 years to 8% of those aged 35–44 years.

Table 2.11.20: Indigenous prison entrants (2010) and the general Indigenous population (2008), labour force status, by age group (per cent)

	Indigenous prison entrants (years)			General Indigenous population (years)		
Employment status	**18–24**	**25–34**	**35–44**	**18–24**	**25–34**	**35–44**
Employed	25	39	34	55	60	66
Unemployed	67	51	40	13	11	8
Not in the labour force	9	11	25	32	29	26

Notes

1. Excludes New South Wales and Victoria, as they did not participate in the 2010 Prison Census.
2. 'Not in the labour force' includes those who are studying, and those who are unable to work.
3. Indigenous data were sourced from entrant forms, National Prisoner Health Census 2010.
4. General Indigenous population data was from AIHW analysis of 2008 National Aboriginal and Torres Strait Islander Social Survey.

Source*:* The health of Australia's prisoners, 2010 (AIHW 2011b).

Mental health

- Indigenous prison entrants reported levels of psychological distress that were similar to or lower than those in the general Indigenous population. Indigenous prison entrants aged 18–34 years were more likely to feel low/moderate psychological distress compared with the general Indigenous population (79–81% and 62–69%, respectively) (Table 2.11.21).

- Similar levels of psychological distress were felt by Indigenous prison entrants and the general Indigenous population aged 35–44 years, in both the low/moderate (67%) and high/very high categories (30–31%).

Table 2.11.21: Indigenous prison entrants (2010) and the general Indigenous population (2008), level of psychological distress as indicated by K5[(a)], by age group (per cent)

	Indigenous prisoners (years)			General Indigenous population (years)		
Level of distress	**18–24**	**25–34**	**35–44**	**18–24**	**25–34**	**35–44**
Low/moderate	79	81	67	62	69	67
High/very high	20	15	30	34	29	31

(a) K5 is the Kessler 5, a psychological distress scale.

Notes

1. Excludes New South Wales and Victoria, as they did not participate in the 2010 Prison Census.
2. Indigenous data were sourced from entrant forms, National Prisoner Health Census 2010.
3. General Indigenous population data was from AIHW analysis of 2008 National Aboriginal and Torres Strait Islander Social Survey.

Source*:* The health of Australia's prisoners, 2010 (AIHW 2011b).

Tobacco smoking

- While it is recognised that relatively high rates of smoking exist in Indigenous communities, rates are still substantially higher among the prison population. Just under half (47%) of the general Indigenous population in Australia smoked tobacco daily, compared with almost three-quarters (74%) of Indigenous prison entrants. And only 10% of Indigenous prison entrants had never smoked a cigarette, compared with 31% of the general Indigenous population (Table 2.11.22).
- Prison entrants aged 18–24 years were the least likely to have never smoked (just 4%), but the most likely among the general population (36%). A similar contrast can be made with those aged 35–44 years: among Indigenous prison entrants, they were the group most likely to have never smoked a cigarette (11%), but within the general Indigenous population, they were the least likely (Table 2.11.23).

Table 2.11.22: Indigenous prison entrants (2010) and the general Indigenous population (2008), tobacco smoking status (per cent)

Smoking status	Indigenous prison entrants	General Indigenous population
Current daily smoker	74	47
Never smoked	10	31

Notes

1. Excludes New South Wales and Victoria, as they did not participate in the 2010 Prison Census.
2. Indigenous data were sourced from entrant forms, National Prisoner Health Census 2010.
3. General Indigenous population data was from AIHW analysis of 2008 National Aboriginal and Torres Strait Islander Social Survey.

Source*:* The health of Australia's prisoners, 2010 (AIHW 2011b).

Table 2.11.23: Prison entrants (2010), the general Indigenous population (2008) and non-Indigenous population (2010) by tobacco smoking status and age group, 2010 (per cent)

	Prisoners (years)			General population (years)		
	18–24	25–34	35–44	18–24	25–34	35–44
			Indigenous			
Never smoked	4	5	11	36	28	27
Ex-smoker	5	2	2	11	16	18

Current smoker	80	84	82	20	23	24

Notes

1. Excludes New South Wales and Victoria, as they did not participate in the 2010 Prison Census.
2. 'Not in the labour force' includes those who are studying, and those who are unable to work.
3. Indigenous data were sourced from entrant forms, National Prisoner Health Census 2010.
4. General Indigenous population data was from AIHW analysis of 2008 National Aboriginal and Torres Strait Islander Social Survey.

Source: The health of Australia's prisoners, 2010 (AIHW 2011b).

Risky alcohol consumption

- Alcohol consumption was higher among Indigenous prison entrants than the general Indigenous population, for both the proportion who drank alcohol and the frequency of consumption. A higher proportion of Indigenous prison entrants reported having consumed alcohol in the previous 12 months compared with the general Indigenous population. (Table 2.11.24).
- Consumption of alcohol four or more times per week was more common among Indigenous prison entrants when compared with those in the general population, although the difference varied. The gap between the age groups in the two populations narrowed from the youngest to the oldest age group. In the general Indigenous population, consuming alcohol 4 or more times per week became more common with age, increasing from 7% for those aged 18–24 years to 13% for those aged 35–44 years; but this trend was not reflected in the prison population.

Table 2.11.24: Indigenous prison entrants (2010) and the general Indigenous population (2008), alcohol drinking status, by age group (per cent)

	Indigenous prison entrants (years)			General Indigenous population (years)		
Alcohol drinking status	18–24	25–34	35–44	18–24	25–34	35–44
4 or more times per week	24	27	25	7	10	13
2–3 times per week	31	23	21	20	14	18
Less than 2–3 times per week	35	42	40	53	55	48

Notes

1. Excludes New South Wales and Victoria, as they did not participate in the 2010 Prison Census.
2. Indigenous data were sourced from entrant forms, National Prisoner Health Census 2010.
3. General Indigenous population data was from AIHW analysis of 2008 National Aboriginal and Torres Strait Islander Social Survey.

Source*:* The health of Australia's prisoners, 2010 (AIHW 2011b).

Illicit drug use

- Among Aboriginal and Torres Strait Islander prison entrants, cannabis/marijuana was the most commonly used drug in 2010. Although rates were substantially lower, this was also true of the general Indigenous population aged 18 years and over. Cannabis/marijuana use was most prevalent in Indigenous Australians aged 18–24 years in both the Indigenous prison entrant population (63%) and the general Indigenous population (23%) (Table 2.11.25).
- While cannabis/marijuana use lessened with age to 13% of Indigenous aged 35–44 years in the general Indigenous population, it remained high at just under half (46%) of Indigenous prison entrants of the same age. Amphetamine and pain killer use for non-medical purposes were also much higher among Indigenous prison entrants when compared with the general Indigenous population (Table 2.11.25).
- Among non-Indigenous prison entrants cannabis/marijuana was also the most commonly used drug. In the youngest age group, non-Indigenous prison entrants were at least twice as likely to report using each type of drug as those in the general community, while non-Indigenous prison entrants aged 35–44 years were at least 3 times as likely to report using each type of drug as those in the general community. Tranquilisers and/or sleeping pills were used illicitly by only 2% of people aged 18–24 years in the general non-Indigenous community, but by almost one-fifth (19%) of non-Indigenous prison entrants in this age group (Table 2.11.25).
- Only 3% of non-Indigenous Australians aged 35–44 years in the general community reported using meth/amphetamines, compared with almost half (47%) of prison entrants (Table 2.11.25).

Table 2.11.25: Prison entrants (2010), the general Indigenous population (2008) and non-Indigenous population (2010) by illicit drug use in previous 12 months, by drug type and age group (per cent)

	Prison entrants (years)			General population (years)		
Illicit drug	**18–24**	**25–34**	**35–44**	**18–24**	**25–34**	**35–44**
			Indigenous			
Cannabis/marijuana	63	55	46	23	20	13
Meth/amphetamine/speed	25	19	18	5	5	1
Analgesics/pain killers	15	23	14	6	5	5
Any illicit drug	**76**	**69**	**68**	**40**	**35**	**29**
			Non-Indigenous			
Cannabis/marijuana	58	61	43	25	20	12
Meth/amphetamine	39	45	47	6	6	3
Analgesics/pain killers	19	17	9	4	3	3
Tranquilisers/sleeping pills	19	18	14	2	2	2
Ecstasy	24	9	13	11	7	2
Any illicit drug	**66**	**79**	**63**	**30**	**26**	**16**

Notes

1. Excludes New South Wales and Victoria, as they did not participate in the 2010 Prison Census.
2. Questions about illicit substance use in the 2008 National Aboriginal and Torres Strait Islander Social Survey were optional, so the per cents in the general population could be an underestimate.
3. Indigenous data were sourced from entrant forms, National Prisoner Health Census 2010;
4. General Indigenous population data was from AIHW analysis of 2008 National Aboriginal and Torres Strait Islander Social Survey.

Source*:* The health of Australia's prisoners, 2010 (AIHW 2011b).

Prisoner health survey data

There have been two recent prisoner health surveys where Indigenous status was recorded, the 2009 New South Wales Inmate Health Survey and the 2002 Queensland Women Prisoners' Health Survey.

- Fewer than half of all male and female prisoners surveyed reported a history of regular injecting drug use. Regular drug use at the time of incarceration, which may include injecting, was reported by 42% of male prisoners in New South Wales, as well as 54% and 63% of female prisoners in New South Wales and Queensland respectively.
- In both surveys, high proportions of prisoners tested positive for communicable diseases, particularly hepatitis C, which is strongly associated with injecting drug use. In New South Wales, the rate of hepatitis C among Indigenous male prisoners rose from 30% in 1996 to 58% in 2004. In comparison, the rate of hepatitis C among non-Indigenous male prisoners has increased only slightly over the same period, from 35% in 1996 to 39% in 2004. The rate of hepatitis C among female Indigenous prisoners also increased slightly, from 72% in 1996 to 75% in 2004. There has been a reduction in the rate of hepatitis C among non-Indigenous female prisoners, from 64% in 1996 to 58% in 2004.
- Approximately 82% of Indigenous prisoners were current smokers compared with 77% of non-Indigenous prisoners, which was over four times the rate of the general population.
- Mental health concerns were common among inmates. In New South Wales, 41% of males and 54% of female inmates reported having received some form of psychiatric

treatment during their lifetime; in Queensland 61% of female inmates had received treatment. Incarceration may be both a risk factor for, and a result of, emotional distress and mental illness. The 1991 Royal Commission into Aboriginal Deaths in Custody found that Aboriginal people who were imprisoned 'often experience depressive symptoms and unresolved anger which sometimes leads them to attempt or commit suicide whilst in custody' (HREOC 1993:698).

- The 1991 Royal Commission also found that the incarceration of young Indigenous men and juveniles during their formative years left them 'permanently alienated from their communities', so that on release from prison, they were likely to turn to substance abuse and violence (HREOC 1993:698).
- Released Aboriginal and Torres Strait Islander prisoners in Western Australia have risk of death almost 10 times that of the general Western Australian population and almost 3 times that of their peers in the community. The main causes of death include suicide, drug and alcohol events, and motor vehicle accidents (Krieg 2006).

Data quality issues

National Prisoner Census

Most jurisdictions collect Indigenous status from individual prisoners. It is uncommon for corrective services agencies to collect Indigenous status from anyone other than the prisoners themselves. However, the accuracy of these data has not been assessed.

The Prisoner Census provides a picture of persons in prison at a point in time (30 June) and does not represent the flow of prisoners during the year. The majority of prisoners in the annual Prisoner Census were serving long-term sentences for serious offences. In comparison, the flow of offenders in and out of prisons consists mainly of persons serving shorter sentences for lesser offences.

The data is extracted from each state and territory's prisoner management and information systems.

Deaths in Custody Australia

As a requirement of the Deaths in Custody Royal Commission, the AIC collects data on deaths in custody each year for all jurisdictions. Indigenous status is by previous self-identification to prison authorities.

Drug Use Monitoring in Australia (DUMA) Survey

The Indigenous status of the detainee is established in the questionnaire by the following questions:

'What is your ethnic background?'(if the respondent mentions 'Australian' but not 'Aboriginal', prompt: 'Do you consider yourself an Aboriginal or Torres Strait Islander?').

It is likely that this question will under-estimates the number of Indigenous persons being detained through a reluctance on the part of detainees to identify as Indigenous.

This survey is conducted at police stations in selected metropolitan areas and does not provide regional coverage. In addition, the actual number of detainees questioned is quite low, which does not permit great analysis of the Indigenous data. Finally, the figures do not permit national coverage, but instead analysis by state is recommended.

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010).

Juvenile Justice National Minimum Data Set

Responsibility for juvenile justice rests at state and territory level, and there is marked diversity in the legislation, policy and practices among jurisdictions. Areas of variation throughout Australia include; the age when young people are considered juveniles or adults by the justice system, key policy directions, diversionary options, possible court outcomes, and specific programs and services available to young people (AIHW 2007). Therefore caution is required in comparing data across the jurisdictions.

Overall, the coverage of data in the JJ NMDS is good. Around 7% of all young people since 2000–01 have an unknown Indigenous status (in 2009–10 this was around 4%), and around 5% of records in each of the order and detention files have unknown or missing information for the postcode and suburb of the young person's usual residence. For all other variables, the proportion of missing data is less than 0.1% (AIHW 2011).

There are a number of additional issues specific to particular states and territories. First, not all states and territories provided JJ NMDS data for 2009–10. Second, not all states and territories were able to provide JJ NMDS data in the new format for all years of the JJ NMDS (2000–01 to 2009–10). For example, complete data for Tasmania are only available from 2006–07, and Western Australia and the Northern Territory did not supply JJ NMDS data for 2008–09 to 2009–10. See Juvenile justice in Australia 2009–10 (AIHW 2011) for more information about JJ NMDS data quality.

Information on Indigenous status has been collected since the implementation of the national data collection, although some differences still exist in how jurisdictions collect the information. Not all jurisdictions use the recommended national standard question and standard codes for recording Indigenous status. However, a number of jurisdictions have recently taken steps to improve their data collection forms and information systems to be more in line with the national standard (AIHW 2012).The calculation of rates for Indigenous and non-Indigenous young people excludes young people with unknown Indigenous status. Rates are not calculated where there are fewer than five young people due to a lack of reliability.

National Prisoner Health Census

Some data are collected with reference to the time period 'within the previous 12 months'. Not all prison entrants had been in prison during the previous 12 months. The proportion of prison entrants who had ever been in prison before was higher among Indigenous than non-Indigenous entrants. Therefore it may be expected that a higher proportion of Indigenous prison entrants may have been in prison during the previous 12 months and had access to prison health services.

Data on prison entrants who attended a clinic due to a communicable disease must be considered with three caveats. First, this is the proportion of all prisoners who attended the clinic for a communicable disease, not the proportion of clinic visits for a communicable disease. Second, this data is a two week sample of clinic attendance and is not related to prevalence data. Finally, the reported data may be an underestimation because prisoners may have attended the clinic for other conditions or symptoms arising from a communicable disease.

List of figures

2.12 Child protection

Aboriginal and Torres Strait Islander children in substantiations, on care and protection orders and in out-of-home care

Data sources

National Child Protection Australia

The National Child Protection (NCP) Data Collection is comprised of data from state and territory child protection administrative data sets, and consists of six sub-collections comprising notifications, investigations and substantiations; care and protection orders; out-of-home care; foster carers; relative/kinship carers; and intensive family support services.

These data are collected each year by the AIHW from the relevant departments in each state and territory. Each state and territory has its own legislation, policies and practices in relation to child protection, which accounts for some of the differences between jurisdictions in the data provided. Australian totals have not been provided for those data that are not comparable across the states and territories.

The reporting process for child protection involves a number of stages. At the notification stage, children in need of protection come into contact with departments responsible for child protection. Notifications may be followed through with an investigation and/or referral to support services. The aim of an investigation is to determine whether notifications are 'substantiated' or 'not substantiated'. A substantiation indicates there is sufficient reason (after an investigation) to believe the child has been, is being, or is likely to be, abused, neglected, or otherwise harmed. In situations where further intervention is required, the child may be placed on a care and protection order and/or in out-of-home care (including foster care and relative/kinship care).

In this collection, children are counted as Indigenous if they are identified as such in the state and territory collections. Children whose Indigenous status is recorded as 'unknown' are excluded, where possible, from calculations of rates and proportions. The counts for Aboriginal and Torres Strait Islander children are therefore likely to be an under-estimate of the actual number of Aboriginal and Torres Strait Islander children in the child protection system.

Note that Tasmania and the Australian Capital Territory have very small numbers, and statistics from these jurisdictions are susceptible to random fluctuations.

Data analyses

Children in substantiated notifications

The data presented for this indicator are from notifications, investigations and substantiations (NIS); care and protection orders (CPO) and out-of-home care (OOHC) collections that the state and territory departments responsible for child protection have provided to the AIHW. Only child protection matters that were notified to state and territory child protection and support services are included in these national collections. Notifications made to other organisations, such as the police or non-government welfare agencies, are included only if these notifications were also referred to state and territory child protection and support services.

Substantiations are defined as situations where, after investigation, the relevant authorities concluded that there was reasonable cause to believe that the child has been, was being or was likely to be abused, neglected or otherwise harmed. Substantiation does not necessarily require sufficient evidence for a successful prosecution and does not imply that treatment or case management was provided (AIHW 2010).

Note that because a child can be the subject of more than one notification, investigation or substantiation in a year, there are fewer children than there are total notifications, investigations and substantiations.

Children in substantiated notifications by age

- In 2010–11, in the majority of jurisdictions, the highest numbers of Indigenous children who were the subject of a substantiated notification were aged between 1 and 4 years. The highest numbers of other children who were the subject of a substantiated notification were aged between 10 and 14 years (Table 2.12.1).

Table 2.12.1: Children in substantiated notifications, by age, Indigenous status and state/territory, 2010–11

Unknown	3	0	0	0	1	1	0	0	5
Total	**8,233**	**6,559**	**4,210**	**1,331**	**1,379**	**986**	**359**	**239**	**23,296**

(a) Following the New South Wales Keep Them Safe reforms, the 2010–11 data reflect the first full year of reporting under legislative changes to the New South Wales Children and Young Persons (Care and Protection) Act 1998, proclaimed on 24 January 2010. This includes raising the reporting threshold from ‘risk of harm’ to the new ‘risk of significant harm’.

(b) Western Australia is currently unable to report a child’s characteristics based on their first substantiation. As a result, a small number of children may be double-counted in this table where they have more than one substantiation and the notifications had differing characteristics such as age or abuse type.

(c) In Tasmania, the proportion of substantiations for children with an unknown Indigenous status affects the reliability of these data.

Notes

1. Finalised investigations, and thus substantiations, refer only to cases that were notified during the year, not the total number of investigations finalised by 31 August 2011.
2. ‘Other children’ includes children whose Indigenous status was unknown.
3. Totals include children of unknown age.
4. The ‘less than 1’ category includes unborn children for New South Wales (428: 154 Indigenous unborn, 274 'other' unborn), Queensland (384: 157 Indigenous unborn, 227 'other' unborn), Western Australia (42: 9 Indigenous unborn, 33 'other' unborn), Tasmania (42: 4 Indigenous unborn, 38 'other' unborn) and the Australian Capital Territory (4: 1 Indigenous unborn, 3 'other' unborn). These children are included in the totals.

Source: AIHW Child Protection Collections 2011.

Substantiated notifications by state/territory

Aboriginal and Torres Strait Islander children are more likely to be the subjects of substantiated notifications than other children. In 2010–11, in all jurisdictions the substantiation rate for Indigenous children was higher than the rate for other children. Across Australia, Indigenous children were more than eight times as likely as non-Indigenous children to be the subject of a substantiated notification (Table 2.12.2).

The reasons for the over-representation of Aboriginal and Torres Strait Islander children in child protection substantiations are complex. The 1997 report *Bringing them home* (HREOC 1997) noted that some of the underlying causes of the over-representation of Aboriginal and Torres Strait Islander children in the child welfare system include:

- the legacy of past policies of the forced removal of Aboriginal children from their families
- intergenerational effects of previous separations from family and culture
- poor socioeconomic status
- perceptions arising from cultural differences in child-rearing practices.

Table 2.12.2: Children aged 0–16 years who were the subjects of substantiations of notifications: number and rates per 1,000 children, by Indigenous status and state/territory, 2010–11

	Number of children					Number per 1,000 children				
State / territory	Indigenous	Non-Indigenous	Unknown no.	Unknown %	All children	Indigenous	Non-Indigenous	All children	Rate ratio Indigenous/ non-Indigenous	Rate Difference[(a)]
NSW[(b)]	3,126	7,860	17	0.2	11,003	46.6	5.3	7.1	8.8	41.3

Aust.	**7,859**	**21,503**	**1,056**	**3.5**	**30,418**	**34.9**	**4.7**	**6.3**	**7.5**	**30.2**

(a) Rate difference equals Indigenous rate minus non-Indigenous rate.

(b) Following the New South Wales Keep Them Safe reforms, the 2010–11 data reflect the first full year of reporting under legislative changes to the New South Wales Children and Young Persons (Care and Protection) Act 1998, proclaimed on 24 January 2010. This includes raising the reporting threshold from ‘risk of harm’ to the new ‘risk of significant harm’.

(c) Western Australia is currently unable to report a child’s characteristics based on their first substantiation. As a result a small number of children may be double-counted in this table where they have more than one substantiation and the notifications had differing characteristics such as age or abuse type.

(d) In Tasmania, the proportion of substantiations for children with an unknown Indigenous status affects the reliability of these data.

Notes

1. Population estimates are based on the 2006 census, refer to Appendix table A1.35 in the 2010–11 Child Protection Australia report for the specific populations used in the calculation of rates.
2. Rate ratios are calculated by dividing the un-rounded rate of Indigenous children who were the subject of substantiations by the un-rounded rate of non-Indigenous children who were the subject of substantiations. The resulting number shows a comparative representation per 1,000 children.
3. Percentage of unknown is the percentage of ‘All children’ in state/territory.
4. The above table excludes unborn children and those in the ‘not stated’ age category.

Source: AIHW analysis of National Child Protection Data Collection 2011.

Substantiated notifications by types of abuse and neglect

Substantiated notifications are classified into four categories depending on the main type of abuse or neglect that has occurred: physical abuse, sexual abuse, emotional abuse and neglect. If a child was the subject of more than one type of abuse or neglect as part of the same notification, the abuse or neglect reported is the one that the child protection workers consider to cause the most harm to the child. Where a child was the subject of more than one substantiation during the year, the type of abuse reported was the one associated with the first substantiation decision during the year. Therefore, it is difficult to measure the overall patterns of types of abuse or neglect that each child may experience.

- For Indigenous children across Australia, the most common type of abuse was neglect. However, in Victoria, Queensland, Tasmania and the Australian Capital Territory, the most common type of abuse for Indigenous children was emotional abuse.
- For non-Indigenous children across most jurisdictions, the most common type of abuse was emotional abuse. However, in Western Australia, South Australia and Australian Capital territory, the most common type of abuse for non-Indigenous children was neglect and in the Northern Territory it was physical abuse (Table 2.12.3).

Table 2.12.3: Children aged 0–17 years who were the subject of a substantiation of a notification: type of abuse or neglect, by Indigenous status and state/territory, 2010–11 (per cent)

Type of abuse or neglect	NSW[(a)]	Vic	Qld	WA[(b)]	SA	Tas[(c)]	ACT	NT	Aust.
Indigenous children									
Physical abuse	19.7	30.3	21.4	20.4	11.1	6.8	25.5	15.9	**19.9**
Sexual abuse	14.4	5.2	5.0	20.6	5.5	4.1	6.6	4.3	**9.7**
Emotional abuse	28.2	56.1	37.1	18.7	29.6	44.5	40.6	26.1	**32.3**
Neglect	37.6	8.3	36.5	40.3	53.8	33.6	27.4	53.6	**37.8**
Total	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**
Other children[(d)]									
Physical abuse	20.2	31.8	21.8	23.0	17.1	15.5	24.5	38.9	**23.8**
Sexual abuse	25.7	10.3	6.7	23.0	7.8	8.0	8.6	9.2	**15.6**
Emotional abuse	27.8	50.7	41.3	19.3	33.6	40.5	29.0	22.6	**37.0**
Neglect	26.3	7.1	30.2	34.7	41.5	32.2	37.9	29.3	**23.4**
Total	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**	**100.0**

(a) Following the New South Wales Keep Them Safe reforms, the 2010–11 data reflect the first full year of reporting under legislative changes to the New South Wales Children and Young Persons (Care and Protection) Act 1998, proclaimed on 24 January 2010. This includes raising the reporting threshold from ‘risk of harm’ to the new ‘risk of significant harm’.

(b) Western Australia is currently unable to report a child’s characteristics based on their first substantiation. As a result, a small number of children may be double-counted in this table where they have more than one substantiation and the notifications had differing characteristics such as age or abuse type.

(c) In Tasmania, the abuse type for some substantiations was recorded as ‘other’ or ‘not stated’ and could not be mapped to physical, sexual, emotional or neglect. These substantiations are included in the totals: as such, totals may not equal the sum of categories. The proportion of substantiations for children with an unknown Indigenous status affects the reliability of these data. As such, comparisons to previous year’s data should be made with caution.

(d) ‘Other children’ includes children whose Indigenous status was unknown.

Notes

1. Finalised investigations, and thus substantiations, refer only to cases that were notified during the year, not the total number of investigations finalised by 31 August 2011.
2. If a child was the subject of more than one type of abuse or neglect as part of the same notification, then the abuse and/or neglect is the one considered by the child protection workers to cause the most harm to the child. Where a child is the subject of more than one substantiation during the year, then the type of abuse reported in this table is the type of abuse and/or neglect associated with the substantiation decision relating to the earliest notification during the year.
3. In Tasmania and the Australian Capital Territory, the proportion of Aboriginal and Torres Strait Islander children who were the subject of a substantiation should be interpreted with caution due to small numbers.
4. Percentages in the table may not add to 100 due to rounding.

Source: AIHW Child Protection Collections 2011.

Time series analyses

Rates of Aboriginal and Torres Strait Islander children aged 0–16 years who were the subject of a substantiation of a notification received during the relevant year, are presented below for all states and territories over the period 2006–07 to 2010–11.

- The highest rates of substantiated notifications received during 2010–11 were within Australian Capital Territory (55 per 1,000 children), while the lowest rates were in Western Australia and Tasmania (18 per 1,000 children) (Table 2.12.4).
- Over the period 2006–07 to 2010–11 there was no significant change to the rate of substantiated notifications received in Australia.

Table 2.12.4: Rates of Aboriginal and Torres Strait Islander children aged 0–16 years who were the subject of a substantiation of a notification received during the relevant year, by state/territory, 2006–07 to 2010–11 (per 1,000 children)

Year	NSW	Vic [(a)]	Qld	WA	SA	Tas[(b)(c)(d)]	ACT[(d)]	NT	Aust
2006–07	53.5	56.6	29.2[(e)]	15.0	39.0	3.9	41.3[(f)]	16.8	34.3
2007–08	53.0	54.9	27.1	17.4	48.1	5.0	46.2	23.7	35.2
2008–09	54.6	48.3	27.0	18.1	50.6	12.6	53.6	24.1	36.1
2009–10	52.7	49.6	26.9	21.1	31.6	16.3	64.6	33.5	36.2
2010–11	46.6	53.3	23.5	17.9	37.6	18.0	55.4	45.5	34.9
Annual change[(g)]	. .	. .	. .	. .	. .	. .	. .	. .	0.2
% Change[(h)]	. .	. .	. .	. .	. .	. .	. .	. .	2.6

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 2006–07 to 2010–11

(a) Due to new service and data reporting arrangements, the Victorian child protection data for 2006–07 onwards may not be fully comparable with previous years' data.

(b) Due to the high number of children with Indigenous status unknown in Tasmania, Indigenous children may be considerably under-reported and comparison of rates from previous years should be conducted with caution.

(c) Data relating to substantiations in Tasmania for 2005–06 and 2006–07 should be interpreted carefully due to the high proportion of investigations in process by 31 August.

(d) Rates from Tasmania and the Australian Capital Territory should be interpreted with care due to small numbers. Any fluctuation in the numbers of children has a large impact on the rates.

(e) 2006–07 data for Queensland was updated in 2008 and may not reflect that interim data originally published in CPA 2006–07.

(f) The decrease in the number of substantiated investigations reflects a requirement of staff to substantiate emotional abuse or neglect only if there was, or is likely to be, significant harm and there was no-one with parental responsibility willing and able to protect the child/young person. Recording an outcome of an appraisal as not substantiated does not exclude ongoing work with the child or young person.

(g) Average annual change in rates, rate ratios and rate differences determined using linear regression analysis.

(h) Per cent change between 2006–07 to 2010–11 based on the average annual change over the period.

Notes

1. From 2007–08 onwards, legislative and policy changes allowed for the capture of data on 'unborn children' as a distinct age grouping. Prior to this year it is not possible to determine whether unborns were included in the less than 1 year age counts and following 2007–08 the 'unborn children' category has been excluded.
2. Some of the rates calculated differ to rate trend data previously reported in AIHW Child Protection collections due to the inclusion of children with a 'not stated' age category and unborn children. The above table excludes unborn children and those in the 'not stated' age category.
3. Population estimates have been updated in 2009 and this may affect rate comparison over time.
4. Due to small numbers and volatility in jurisdiction level data, significance testing of trends was only calculated for Australia level data.

Source: AIHW analysis of National Child Protection Data Collection 2011.

Care and protection orders

If a child has been the subject of a child protection substantiation, there is often a need for state and territory child protection and support services to have continued involvement with the family. The relevant department generally attempts to protect the child through the provision of appropriate support services to the child and family. In situations where further intervention is required, the department may apply to the relevant court to place the child on a care and protection order.

Recourse to the court is usually a last resort—for example, where the family resists supervision and counselling, where other avenues for resolution of the situation have been exhausted, or where removal of the child to out-of-home care needs legal authorisation. However, not all applications for an order will be granted. The term 'care and protection order' refers not only to legal orders but also to other legal processes relating to the care and protection of children, including administrative arrangements or care applications (AIHW 2010).

Care and protection orders by age

- At 30 June 2011, the highest numbers of Indigenous children who were on care and protection orders were aged 5–9 and 10–14 years. This trend also applied to other children (Table 2.12.5).

Table 2.12.5: Children on care and protection orders, by age, Indigenous status and state/territory, at 30 June 2011

(a) New South Wales data do not include children on finalised supervisory orders.

(b) Numbers for Tasmania are over reported due to considerable data lag with the recording of order status.

(c) 'Other children' includes those children whose Indigenous status was unknown.

(d) Percentages exclude children of unknown age.

(e) Percentages in tables may not add to 100 because of rounding.

Source: AIHW analysis of National Child Protection Data Collection 2011.

Care and protection orders by state/territory

- As at June 2011, the rates of Aboriginal and Torres Strait Islander children on care and protection orders varied considerably across jurisdictions, ranging from 21 per 1,000 in the Northern Territory to 91 per 1,000 in the Australian Capital Territory (Table 2.12.6).
- In all jurisdictions, the rate of Indigenous children on care and protection orders was higher than the rate for non-Indigenous children, ranging from 3 to 15 times as high across jurisdictions. Nationally, the rate of Indigenous children on orders was 10 times that of non-Indigenous children.

Table 2.12.6: Children on care and protection orders: number and rate (number per 1,000 children aged 0–17 years), by Indigenous status and state/territory, at 30 June 2011

(a) Includes children whose Indigenous status was unknown.

(b) Rate difference equals Indigenous rate minus non-Indigenous rate.

(c) New South Wales data do not include children on finalised supervisory orders.

(d) Numbers and rates for Tasmania are over reported due to considerable data lag with the recording of order status.

Notes

1. Percentage of unknown is the percentage of ‘All children’ in state/territory.
2. Population estimates are based on the 2006 census, refer to Appendix table A1.35 in the 2010–11 Child Protection Australia report for the specific populations used in the calculation of rates.
3. Rate ratios are calculated by dividing the un-rounded rate of Indigenous children who were on a care and protection order by the un-rounded rate of non-Indigenous children who were on a care and protection order. The resulting number shows a comparative representation per 1,000 children.
4. The above table excludes children in the ‘not stated’ age category.

Source: AIHW analysis of National Child Protection Data Collection 2011.

Types of care and protection orders

There were more orders issued during 2010–11 than children admitted to orders because more than one order can be issued for any one child. For example, a child will often be admitted to a temporary or interim order followed by a guardianship or custody order. The orders issued in 2010–11 for Indigenous and other children are presented in Table 2.12.7.

- As at 30 June 2011, most Indigenous children on care and protection orders were on guardianship and custody orders or arrangements (73%). The types of orders that Indigenous children were on compared with other children were very similar; however, Indigenous children were generally less likely to be on third-party parental responsibility or supervisory orders than other Australian children.

Table 2.12.7: Children on care and protection orders, by type of order, by state/territory and Indigenous status, 30 June 2011

(a) New South Wales data do not include children on finalised supervisory orders.

(b) In Western Australia, the application for a care and protection order to be issued for a child is counted as an interim order for national reporting purposes. However, there is, in fact, no order issued during this stage. It is thus not valid to compare the number of orders by a percentage basis.

(c) Numbers for Tasmania are over reported due to considerable data lag with the recording of order status.

(d) Includes children whose Indigenous status was unknown.

Note: Percentages in the table may not add to 100 due to rounding.

Length of time on care and protection orders

- In 2010–11, in New South Wales and the Northern Territory, Indigenous children were most likely to be on care and protection orders for less than 1 month. In Victoria, Queensland, Western Australia and South Australia, Indigenous children were most likely to be on care and protection orders for a period of 2 years to less than 4 years. In Tasmania, Indigenous children were most likely to be on care and protection orders for 1 year to less than 2 years. In the Australian Capital Territory Indigenous children were most likely to be on care and protection orders for 8 years or more (Table 2.12.8).
- A similar pattern was evident for other children on care and protection orders in 2010–11 for most states and territories, with the exception of South Australia, Tasmania and the Australian Capital Territory.

Northern Territory	30.6	19.4	6.9	2.8	12.5	15.3	8.3	4.2	**100.0**

(a) New South Wales data do not include children on finalised supervisory orders.

(b) Numbers for Tasmania are under reported due to considerable data lag with the recording of order status.

(c) Other children' includes those children whose Indigenous status was unknown.

Notes

1. If a child is discharged from an order and a new care and protection order/arrangement is applied within 5 days of the discharge, the orders are deemed to be consecutive (i.e. the length of time continuously on an order will include both orders).
2. If a child is on multiple care and protection orders/arrangements, all orders/arrangements must be discharged before a discharge for the purposes of this table is counted.
3. Length of time continuously on an order is counted only for the first order/arrangement that the child is discharged from during the year.
4. Totals exclude discharges of unknown length.
5. Percentages in tables may not add to 100 due to rounding.

Source: AIHW analysis of National Child Protection Data Collection 2011.

Time series analyses

The number of children aged 0–17 years on care and protection orders by Indigenous status and state and territory is reported for the period of 2007–2011 in Table 2.12.9 and Figure 2.12.1.

- As at 30 June 2011 there were 12,280 Aboriginal and Torres Strait Islander children on care and protection orders, an increase of 65% since June 2007. There was a 21% increase for other children over the same period.

Table 2.12.9: Number of children on care and protection orders: children aged 0–17 years, by Indigenous status and state/territory, at 30 June 2007 to 30 June 2011

(continued)

Table 2.12.9 (continued): Number of children on care and protection orders: children aged 0–17 years, by Indigenous status and state/territory, at 30 June 2007 to 30 June 2011

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 2007 to 2011.

(a) Average annual change in rates, rate ratios and rate differences determined using linear regression analysis.

(b) Per cent change between 2007 and 2011 based on the average annual change over the period.

(c) New South Wales data do not include finalised supervisory orders.

(d) Because of new service and data reporting arrangements, the Victorian child protection data from 2006–07 may not be fully comparable with previous years data. See AIHW (2008) for more information.

(e) 2007 data for Queensland published in *Child protection Australia* were interim and were revised in 2008.

(f) 2007 data include 24 children who were placed on Enduring Parental Responsibility orders.

(g) Numbers for Tasmania for 2010 and 2011 are over reported due to considerable data lag with the recording of order status.

(h) Additional systems have been put in place to tackle the Indigenous status recording issues, including quarterly monitoring.

(i) Other children includes those children whose Indigenous status was unknown. Children of unknown Indigenous status were not collected at a national level until 2006–07; hence interpretation of these trend data should therefore be treated with caution.

Notes

1. The counts of Aboriginal and Torres Strait Islander children are likely to be an underestimate of the actual number of Aboriginal and Torres Strait Islander children in the child protection system.
2. Due to small numbers and volatility in jurisdiction level data, significance testing of trends was only calculated for Australia level data.

Figure 2.12.1: Indigenous children aged 0–17 years on care and protection orders as at 30 June 2007 to 30 June 2011

Out-of-home care

Out-of-home care is one of a range of services provided to children and young people under 18 years of age who are in need of care and protection. This service provides alternative accommodation to children and young people who are unable to live with their parents. These arrangements include foster care, placements with relatives or kin, and residential care. In most cases, children in out-of-home care are also on a care and protection order of some kind.

Some children are placed in out-of-home care because they are the subject of a child protection substantiation and require a more protective environment. Other situations in which a child may be placed in out-of-home care include those whose parents are incapable of providing adequate care for the child, or where alternative accommodation is needed during times of family conflict. There are no national data available, however, on the reasons children are placed in out-of-home care. This is expected to change with the introduction of the unit record collection which is currently being developed (AIHW 2010).

Out-of-home care by state/territory

- At 30 June 2011, there were 12,358 Aboriginal and Torres Strait Islander children aged 0–17 years in out-of-home care. The rate was 52 per 1,000, ranging from 18 in the Northern Territory to 81 in New South Wales (Table 2.12.10).
- In all jurisdictions there were higher rates of Indigenous children in out-of-home care than non-Indigenous children. The national rate of Indigenous children in out-of-home care was 10 times that for non-Indigenous children.

Table 2.12.10: Children in out-of-home care: number and rate (number per 1,000 children aged 0–17 years), by Indigenous status and state/territory, at 30 June 2011

	Number of children					Number per 1,000 children				
State/ territory	Indigenous	Non-Indigenous	Unknown no.	Unknown %	All children[(a)]	Indigenous	Non-Indigenous	All children[(a)]	Rate ratio Indigenous/ non-Indigenous	Rate difference[(b)]

Australia	**12,358**	**24,929**	**361**	**1.0**	**37,648**	**51.7**	**5.1**	**7.3**	**10.1**	**46.6**

(a) Includes children whose Indigenous status was unknown.

(b) Rate difference equals Indigenous rate minus non-Indigenous rate.

Notes

1. Percentage of unknown is the percentage of ‘All children’ in state/territory.
2. Population estimates are based on the 2006 Census; refer to Appendix table A1.35 in the 2010–11 Child Protection Australia report for the specific populations used in the calculation of rates.
3. Rate ratios are calculated by dividing the un-rounded rate of Indigenous children who were in out-of-home care by the un-rounded rate of non-Indigenous children who were in out-of-home care. The resulting number shows a comparative representation per 1,000 children.
4. The above table excludes children in the ‘not stated’ age category.

Out-of-home care by Indigenous status of caregivers

The Aboriginal Child Placement Principle outlines a preference for the placement of Aboriginal and Torres Strait Islander children with other Aboriginal and Torres Strait Islander people when they are placed outside their family (Lock 1997:50). The principle has the following order of preference for the placement of Aboriginal and Torres Strait Islander children:

- with the child's extended family
- within the child's Indigenous community
- with other Indigenous people.

All jurisdictions have adopted the Aboriginal Child Placement Principle either in legislation or policy. The impact of the Principle is reflected in many jurisdictions in the relatively high proportions of Aboriginal and Torres Strait Islander children who were placed either with Indigenous caregivers or with relatives.

It is important to note that the Aboriginal Child Placement Principle is just one of the many considerations taken into account when making decisions on placements for Indigenous children. Where placement options outlined in the principle are not optimal for a child's safety and wellbeing, the child may be placed in an alternative care arrangement; this is usually only done after extensive consultation with Indigenous individuals and organisations.

- As at 30 June 2011, the proportion of Aboriginal and Torres Strait Islander children who were placed with either an Indigenous carer or a relative was above 50% except for Tasmania (43%) and the Northern Territory (34%). In New South Wales, 82% of Indigenous children were placed with relative/kin, other Indigenous caregivers or in Indigenous residential care (Table 2.12.11).

Table 2.12.11: Aboriginal and Torres Strait Islander children in out-of-home care: Indigenous status and relationship of carer, by state/territory, at 30 June 2011

Data quality issues

Child protection data

Reported rates for Aboriginal and Torres Strait Islander children in the child protection system for 2008–09, 2009–10 and 2010–11 cannot be compared directly with previous years data published in AIHW Child protection in Australia reports. In previous years, rates were calculated using ABS Indigenous population denominators from the 1996 and 2001 Census, while the 2008–09, 2009–10 and 2010–11 rates are based on the 2006 census population data. For time series analyses presented in this measure, rates were taken from the published reports and they have not been re-calculated using recent Indigenous population estimates based on 2006 Census.

State/territory comparisons

As each state or territory has a different legal regime and different human services policies around child protection, states and territory comparisons should be made with caution. Tasmania and the Australian Capital Territory have very small numbers, and statistics from these jurisdictions are susceptible to random fluctuations.

Child protection is an area in which legislation and human services practice changes. Often notification rates vary owing to public awareness of child abuse, and practices in relation to the intensity of follow-up of notifications which are affected by a number of factors. For these reasons time series comparisons may not be statistically valid.

In addition, one-off global changes may occur in the legal and procedural regime of a particular jurisdiction, which may make comparisons between time series data from before and after such change invalid.

Child abuse

Child protection policies and practices are continually under development. As such, they impact on the number of children in the child protection system in different ways. Therefore, trends in child protection numbers should be interpreted carefully.

The definition of what constitutes child abuse and neglect has changed and broadened over time (AIFS: Bromfield & Holzer 2008). Naturally, any broadening of the definition of child abuse and neglect is likely to increase notifications and substantiations. The focus of child protection in many jurisdictions has shifted away from the identification and investigation of narrowly defined incidents of child abuse and neglect. Instead, the focus has moved towards a broader assessment of whether a child or young person has suffered harm.

Care and protection orders

For the 2010–11 financial year Indigenous children are counted only once, even if they were admitted to or discharged from more than one order or were on more than one order at 30 June 2011. If a child is on more than one order at 30 June, 2011, then they are counted as being on the order that implies the highest level of intervention by the department (with guardianship or custody orders being the most interventionist, and interim and temporary orders the least) (AIHW 2012).

Substantiations

Since 1997 the number of substantiated notifications of child abuse across Australia has increased significantly. Therefore, interpretation of the figures for Indigenous children should be in the light of the increasing number of all children subject to these substantiated notifications.

Indigenous status

Information on Indigenous status may be collected at each stage of a child protection case; this varies by jurisdiction, with some collecting only at the investigation stage, others at the notification and investigation stages, and others at all stages. However, data are not reported at the notification stage as the quality of these data is questionable, as many notifications are from third parties who do not know the child or family well.

The practices used to identify and record the Indigenous status of children in the child protection system also vary across states and territories, with some jurisdictions recording large numbers of children with unknown Indigenous status. No state or territory can validate the data on Aboriginal and/or Torres Strait Islander children by other means and the quality of the data is therefore unknown. Over the last few years, several jurisdictions have introduced measures to improve the identification of Indigenous children in the child protection system. However, in some jurisdictions the quality of data on Aboriginal and/or Torres Strait Islander children is still affected by the high proportion of children whose Indigenous status is unknown. The counts for Aboriginal and Torres Strait Islander children are therefore likely to be an under-estimate of the actual number of Aboriginal and Torres Strait Islander children in the child protection system.

List of figures

2.13 Transport

The use of transport, including walking, access to motor vehicles and perceived difficulty with transport among Aboriginal and Torres Strait Islander people.

Data sources

Data for this measure come from the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS).

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Data analyses

Motor vehicle access

- Results from the 2008 NATSISS indicate that approximately 51% of Indigenous households had access to a working motor vehicle in 2008.
- In 2008, around 78% of Indigenous people aged 18 years and over had access to a working motor vehicle to drive compared with 86% of non-Indigenous people.

Motor vehicle access by remoteness

- In 2008, approximately 50% of Indigenous households in non-remote areas reported having access to at least one motor vehicle compared with 57% of Indigenous households in remote areas. In Other Australian households, access to motor vehicles in non-remote areas was 85% (Table 2.13.1).
- Other households in *Outer Regional* areas were most likely to have access to a vehicle (90%) while Indigenous households were most likely to have access to a vehicle when located in *Inner Regional* areas (54%) (Table 2.13.1).

Table 2.13.1: Proportion of households with and without access to motor vehicles, by Indigenous status and remoteness, 2008

	Without motor vehicle access		With motor vehicle access		Total	
	Indigenous households	**Other households**	**Indigenous households**	**Other households**	**Indigenous households**	**Other households**

Motor vehicle access by age

- Of Indigenous people aged 18 years and over, Indigenous people aged 18–24 years were least likely to have access to a motor vehicle (70%), followed by Indigenous people 55 years and over (73%) (Table 2.13.2).

Table 2.13.2: Access to motor vehicles for persons aged 18 years and over, by Indigenous status and age, 2008

Transport access, difficulty and use

The 2008 NATSISS collected data on access to transport, perceived level of difficulty with transport, use of transport (including public transport) in the 2 weeks before the survey, modes of transport, and reasons for not using public transport. These data are presented below.

- Around 6.5% of Indigenous persons aged 18 years and over reported they could only access a motor vehicle in an emergency and 8% could not access a motor vehicle but could drive (Table 2.13.3).
- Around 11% of Indigenous Australians aged 18 years and over reported that they could not get to or often had difficulty getting to the places they needed to, compared with only 4% of non-Indigenous Australians (Table 2.13.4).
- Approximately 26% of Indigenous Australians aged 18 years and over used public transport in the previous 2 weeks and a further 72% used other forms of transport (Table 2.13.6).
- Of those who used transport in the previous 2 weeks, the most common mode of transport was a car or 4WD as a passenger (63%), followed by a car/4WD as a driver (55%) and walking (55%) (Table 2.13.7).

- The main reasons given for not using public transport in the previous 2 weeks were 'prefer to use own transport or walk' (32%) and 'no service available in local area' (32%) (Table 2.13.5).

Transport access, difficulty and use by age and sex

- Indigenous Australians aged 18–24 years were more likely to report they could only access a motor vehicle in an emergency (Table 2.13.3), and to have used public transport in the previous 2 weeks (31%) than those in older age groups (Table 2.13.6).
- A higher proportion of Indigenous males than Indigenous females reported having access to a motor vehicle (81% compared with 75%) (Table 2.13.8).
- A higher proportion of Indigenous females reported using public transport in the previous 2 weeks than Indigenous males (28% compared with 23%) (Table 2.13.8).

Transport access, difficulty and use by state/territory

- Indigenous Australians in every state and territory were much more likely than non-Indigenous Australians to report having difficulty getting to the places they needed to. Indigenous Australians living in the Northern Territory were five times as likely, and in Western Australia were three times as likely, to have had difficulty getting to the places needed compared to non-Indigenous Australians in these states and territories (Table 2.13.10).
- In all states and territories, except for Tasmania, Indigenous Australians were less likely to have access to motor vehicles (Table 2.13.9).
- Indigenous Australians in Tasmania were least likely to have used public transport in the 2 weeks before the survey compared to those in other states and territories (Table 2.13.12).
- In all states and territories Indigenous Australians described the main reason they did not use public transport was because they prefer to use their own transport or walk. This ranged from 48% in the Australian Capital Territory to 23% in the Northern Territory (Table 2.13.11).

Transport access, difficulty and use by remoteness

- In non-remote areas, a higher proportion of Indigenous Australians reported having access to a motor vehicle to drive than Indigenous Australians in remote areas (81% compared with 70%) (Table 2.13.14).
- In remote areas, Indigenous Australians were more likely to report that they could not get to or often had difficulty getting to the places they needed to (18%) than Indigenous Australians in non-remote areas (8%) (Table 2.13.14).
- In remote areas, Indigenous Australians were much more likely to report not having used transport in the previous 2 weeks (7%) than in non-remote areas (1%). In remote areas, unavailability of public transport in local area (83%) was the main reason for not using public transport (Table 2.13.14).

Table 2.13.14: Transport, by Indigenous status and remoteness, persons aged 18 years and over, 2008

	Non-remote			Remote			Total

Transport difficulty by selected health and population characteristics

Tables 2.13.16 and 2.13.17 present information on Indigenous persons aged 18 years and over, by perceived level of difficulty with transport and selected health and population characteristics. Proportions in Table 2.13.16 are calculated within a column using the total across the rows as a denominator; while proportions in Table 2.13.17 are calculated within a row using the column totals as a denominator.

- A higher proportion of both Indigenous and non-Indigenous Australians aged 18 years and over who could not get to places when needed reported fair/poor health status and having a disability or long-term health condition than Australians who could easily get to places when needed (Table 2.13.16).
- A higher proportion of Indigenous Australians who could not get to places when needed were in the lowest (1st) quintile of household income and reported they could not raise $2,000 within a week for something important than Indigenous Australians who could easily get to places when needed (Table 2.13.16).

Transport/distance as a barrier to accessing health services

The 2008 NATSISS collected information on reasons Indigenous Australians didn't visit a dentist, doctor, other health professional or hospital when needed, including transport/distance. These data are presented below and can be found in Indicator 3.12.

- In 2008, 10% of Indigenous Australians reported that transport/distance was a reason they had problems accessing a service.
- A higher proportion of Indigenous people living in remote areas (19%) than in non-remote areas (7%) reported transport/distance as a reason for not accessing health services.
- Indigenous Australians aged 25–34 years were more likely than those in older age groups to report transport as the main reason they didn't access health services when needed.
- Indigenous females (11%) were more likely than males (8%) to report transport/distance as the main reason they didn't access a doctor or hospital in the previous 12 months when needed (See Indicator 3.12 for more details).

The data on vehicles per household and per person presented in this indicator suggest that non-Indigenous Australians have better access to personal transport than Indigenous Australians and would therefore be more readily able to reach a health facility or service. Public transport may compensate for the lack of personal transport, and clinics may provide a transport service for their patients, but these services are not available everywhere. The main reason given by 33% of those who sometimes have difficulty in getting to the places they needed to and did not use public transport in the 2 weeks before the survey was that no service was available (Table 2.13.18).

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82 per cent of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS as the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may however be used to obtain rough non-Indigenous comparisons for some data items. Where possible ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

There was a relatively large level of under-coverage and caution should be exercised when interpreting the survey results. The under-identification of Indigenous persons in non-community areas is estimated to be up to 31% of those screened. This estimate is the remaining level of undercoverage when all other known sources of undercoverage have been removed. Part of this percentage is likely to be due to other factors which are unknown. (ABS 2010)

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: users' guide 2008* (ABS 2010).

List of tables

2.14 Indigenous people with access to their traditional lands

The proportion of Aboriginal and Torres Strait Islander people living on or visiting traditional areas of land with which they have ancestral and/or cultural links

Data sources

Data for this indicator come from the 2008 National Aboriginal and Torres Strait Islander Social Survey.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Data analyses

Access to traditional lands

- In 2008, approximately 71% of Indigenous Australians aged 15 years and over reported they recognised their homeland or traditional country. Approximately 26% reported they lived on their homeland, 45% were allowed to visit their homeland and 1% were not allowed to visit their homeland/traditional country (Table 2.14.1).

Access to traditional lands by age group

- In 2008, the proportion of Indigenous Australians aged 15 years and over who reported they recognised their homelands was highest among those aged 35–44 years (81%) and lowest among those aged 15–34 years (65%) (Table 2.14.1).
- In 2008, only 39% of 15–34 year olds were allowed to visit homelands/traditional country compared with 51–53% of all other age groups (Table 2.14.1).

Table 2.14.1: Access to homelands/traditional country, by age group, Indigenous Australians, 2008

	Does not recognise homelands/ traditional country	Recognises homelands/traditional country				Total

Access to traditional lands by state/territory

- The proportion of Indigenous Australians who reported they recognised their homelands varied by jurisdiction, being highest in the Northern Territory *Remote* and *Very remote* areas (91%) and lowest in New South Wales *Major Cities* (57%) (Table 2.14.2).
- The proportion of Indigenous Australians who lived on their homeland was highest in the Northern Territory *Remote* and *Very remote* areas (48%) and lowest in Queensland *Major Cities* (3%).
- The proportion of Indigenous people who were allowed to visit their homelands/traditional country was highest in Queensland *Major cities* (71%) and lowest in *Remote* and *Very remote* areas of New South Wales, South Australia and Tasmania combined (23%).

Access to traditional lands by remoteness

- In general, the proportion of Indigenous Australians aged 15 years and over who reported they recognised their homelands in 2008 increased with remoteness. The highest proportion was in *Very remote* areas (90%) and lowest was in Inner Regional areas (63%) (Table 2.14.3).
- Around 44% of Indigenous Australians reported they lived on their homeland in remote areas, and 19% in non-remote areas (Table 2.14.3).
- The proportion of Indigenous people who were allowed to visit their homelands/traditional country but did not live there was highest in *Major cities* (55%) (Table 2.14.3).

Access to traditional lands by remoteness and selected population and socioeconomic characteristics

- In 2008, Indigenous Australians who recognised their homelands and lived in remote areas were more likely to be living under financial stress (68%) then those in non-remote areas (47%) (Table 2.14.4).
- Total employment rates for those who recognised their homelands and lived in remote areas were lower (50%) than those who lived in non-remote areas (53%). Similar rates by remoteness were observed for those who have access to homelands (Table 2.14.4).

Access to traditional lands by selected health characteristics

- In 2008, among Indigenous Australians aged 15 years and over who recognised and lived on their homelands/traditional country, 79% were in excellent/very good health status and 21% were in fair/poor health status. Among Indigenous Australians who recognised and was allowed to visit their homelands/traditional country, 76% were in excellent/very good health status and 24% were in fair/poor health status. Among Indigenous Australians who recognised but did not live on and was not allowed to visit their homelands/traditional country, 42% were in excellent/very good health status and 58% were in fair/poor health status (Table 2.14.5).
- The proportions of Indigenous Australians aged 15 years and over who recognised and lived on their homelands/traditional country were similar between different levels of health status, levels of selected risk factors and levels of psychological distress. The proportions ranged from 24% (fair/poor health status, low risk alcohol consumption) to 28% (medium/ high risk alcohol consumption). Similar patterns were observed for proportions of Indigenous Australians aged 15 years and over who did not recognise their homelands/traditional country, and proportions of Indigenous Australians aged 15 years and over who recognised but did not live on and was not allowed to visit their homelands/traditional country (Table 2.14.6).

Access to traditional lands by community cohesion

- In 2008, 90% of Indigenous Australians aged 15 years and over who recognised and lived on their homelands had support in a time of crisis, 88% of those who did not recognised their homelands had support in a time of crisis (Table 2.14.7).
- A higher proportion of Indigenous Australians who recognised their homelands and lives there reported neighbourhood problems (75%), compared with 67% of those who recognise their homelands but are not allowed to visit or live there (Table 2.14.7).

Access to traditional lands by personal stressors

- In 2008, 28% of Indigenous Australians who lived on their homelands reported a death of a family member or close friend, 11% reported difficulty in getting a job and 10% reported overcrowding (Table 2.14.9).
- Around 30% of Indigenous people who recognised their homelands but were not allowed to visit reported a death of a family member or close friend and 21% reported divorce or separation (Table 2.14.9).

Frequency and length of time spent visiting homelands

- In 2008, of Indigenous Australians 15 years and over who recognised and were allowed to visit their homelands, 49% visited their homelands less than once a year. This was compared with only 2% that visited their homelands at least weekly and 2% who visited their homelands fortnightly (Table 2.14.10).
- In 2008, of Indigenous Australians 15 years and over who visited their homelands at least once a year, 43% reported the longest time that they spent at their homelands was one week to less than a month. This was compared with 2.2% that reported three to less than six months (Table 2.14.11)

Length of time spent visiting homelands by health status and risk factors, psychological distress, community cohesion and personal stressors

- For those Indigenous Australians who reported spending 3 to less than 6 months visiting their homelands, 83% reported excellent/very good/good health compared with 17% who reported fair/poor health (Table 2.14.12).
- Of those who spent less than a week visiting their homelands, 78% reported excellent/very good/good and 22% reported fair/poor health (Table 2.14.12).
- Indigenous Australians who spent 6 months or more visiting their homelands were more likely to be a daily smoker, use risky amounts of alcohol and to have ever used substances (63%, 30% and 46%, respectively) than those who spent less than a week visiting their homelands (44%, 17% and 43%, respectively) (Table 2.14.13; Table 2.14.15).
- Of Indigenous Australians who reported that they did not have support during a time of crisis 11% has spent less than a week visiting their homelands in the past year while 2.1% had spent 3 to less than 6 months visiting their homelands (Table 2.14.12).

Identification with clan, tribal or language group

- The level of identification with a clan, tribal or language group was highest within the 35–44 year age group where 72% of Indigenous Australians reported identifying with their clan, tribal or language group. Identification was lowest for the 15–24 year age group where only 51% identified with the clan, tribal or language group (Table 2.14.16).

Table 2.14.16: Whether identifies with clan, tribal or language group, by age, 2008

	15–24 years	25–34 years	35–44 years	45–54 years	55 years and over
Identifies with clan, tribal or language group	50.6	63.9	71.8	68.2	66.0

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors

Care has been taken to ensure that the results of this survey are as accurate as possible. All interviews were conducted by trained ABS officers. However, some factor may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However, not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys; hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS as the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may however be used to obtain rough non-Indigenous comparisons for some data items. Where possible ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS user’s guide (ABS 2010).

Data sources

Data for this indicator come from the 2004–05 National Aboriginal and Torres Strait Islander Health Survey, the 2008 National Aboriginal and Torres Strait Islander Social Survey.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of areas of social concern including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

Data analyses

NATSISS data

Smoking prevalence data presented below are from the 2008 NATSISS, with non-Indigenous comparisons from the 2007–08 National Health Survey.

- In 2008, approximately 48% of Indigenous Australians aged 18 years and over reported they were current daily smokers, 2% were current smokers weekly or less than weekly; 21% were ex-smokers and 29% reported that they had never smoked (Table 2.15.1).
- Indigenous Australians were more than twice as likely to be current daily smokers as non-Indigenous Australians (Table 2.15.1).

Smoking status by age group and sex

- A higher proportion of Indigenous males aged 18 years and over were current daily smokers compared to females of the same age (50% compared with 46%) (Table 2.15.1).
- The highest proportion of current daily smokers were among Indigenous persons aged 25–34 years (53%) (Table 2.15.1).
- Around one in five (20%) of Indigenous persons aged 15 to 17 years were current daily smokers. The rate ratio of Indigenous smokers to non-Indigenous smokers was also greatest at this age group (Table 2.15.1 and Table 2.15.2).
- The rate ratio of Indigenous to non-Indigenous smokers ranged from 3.2 in persons aged 15 to 17 years, to 2.2 for age groups 25–34, 35–44 and 45–54 years (Table 2.15.2).
- A rate ratio of Indigenous to non-Indigenous daily smokers were higher among females (5.0) aged 15–17 years than for males (2.2) in the same age group (Table 2.15.2).

* Represents results with statistically significant differences at the p<0.05 level in the Indigenous/non-Indigenous comparisons.

(a) Comprises persons who smoked at least once a week, but not daily, and those who smoked less than weekly.

(b) Estimate has a relative standard error between 25% and 50% and should be used with caution.

(c) Estimate has a relative standard error greater than 50% and is considered too unreliable for general use.

(d) The rate ratio is calculated by dividing the rate for Indigenous persons by the corresponding rate for non-Indigenous persons.

Smoker status by state/territory

- In 2008, the proportion of Indigenous persons aged 18 years and over who were current smokers ranged from 38% in the Australian Capital Territory to 55% in the Northern Territory (Table 2.15.3). The proportion of Indigenous persons aged 15 years and over who were current smokers ranged from 36% in the Australian Capital Territory to 53% in the Northern Territory (Table 2.15.4).
- The proportion of Indigenous ex-smokers aged 18 years and over in 2008 ranged from 14% in the Northern Territory to 29% in the Australian Capital Territory (Table 2.15.3) The proportion of Indigenous ex-smokers aged 15 years and over in 2008 ranged from 13% in the Northern Territory to 26% in the Australian Capital Territory (Table 2.15.4).
- The proportion of Indigenous persons aged 18 years and over who reported that they had never smoked was lowest in New South Wales (25%) and highest in the Australian Capital Territory (34%) (Table 2.15.3). The proportion of Indigenous persons aged 15 years and over who reported that they had never smoked was lowest in New South Wales (30%) and highest in the Australian Capital Territory (38%) (Table 2.15.4).
- Indigenous Australians were between 2.5 and 2.6 times as likely to be current daily smokers when compared to non-Indigenous Australians in all states and territories (Table 2.15.5; Table 2.15.6).

Smoker status by remoteness

- In 2008, the proportion of Indigenous persons aged 18 years and over who were current smokers ranged from 45% in *Major cities* to 56% in the *Very remote* areas (Table 2.15.7). The proportion of Indigenous persons aged 15 years and over who were current smokers ranged from 42% in *Major cities* to 55% in *Very remote* areas (Table 2.15.8).
- For Indigenous persons 18 years and over, *Major cities* had the greatest proportion of ex-smokers (25%) and persons who had never smoked (31%). *Very remote* areas had the lowest proportion of ex-smokers (15%) and *Outer regional* areas had the lowest proportion of persons who had never smoked (26%) (Table 2.15.7). For Indigenous persons 15 years and over, *Major cities* had the greatest proportion of persons who had never smoked (36%) and *Outer regional* areas had the lowest proportion of persons who had never smoked (30%) (Table 2.15.8).

Smoking status over time

- From 2002 to 2008, the percentage of Indigenous persons aged 15 years and over who were current smokers increased from 33% to 45% and the proportion that had never smoked decreased from 49% to 31%. Over the same period, the proportion of ex-smokers increased from 2.3% to 24% (Table 2.15.9).
- From 1994–1995 to 2001–2002, the proportion of Indigenous persons aged 18 years and over in non-remote areas who were current smokers dropped from 55% to 52%. (Table 2.15.10).
- From 1994 to 2008, the proportion of Indigenous males aged 15 years and over who were smokers decreased from 55% to 49%. The percentage for females decreased from 49% to 45% (Table 2.15.11).
- Over the same period, the biggest decrease of any age-group was in the 15–17 year old group were the percentage of smokers dropped from 30% to 22% (Table 2.15.11).

Smoker status by population characteristics

- In 2008, Indigenous Australians aged 18 years and over were more likely to report being a current smoker if they were in the lowest (1st) household income fifth than if they were in the highest (57% compared with 37%); were in the most disadvantaged (socio-economic index for areas) quintile (1st) than if they were in the least disadvantaged (56% compared with 32%); and if they were unemployed than if they were employed (68% compared with 45%) (Table 2.15.12).
- Indigenous Australians were more likely to report being a current smoker if they did not have a non-school qualification than if they did (53% compared with 44%) or if the highest year of schooling completed was Year 9 or below than if they completed Year 12 (57% compared with 36%) (Table 2.15.12).
- Indigenous Australians aged 18 years and over were more likely to report being a current smoker if they reported high/very high levels of psychological distress than if they had low levels of distress (59% compared with 46%); and if they drank at risky/high-risk levels than if they did not (66% compared with 46%) (Table 2.15.12).
- Indigenous Australians aged 15 years and over were more likely to report being a current smoker if they reported high/very high levels of psychological distress than if they had low levels of distress (57% compared with 43%); and if they drank at risky/high-risk levels than if they did not (66% compared with 42%) (Table 2.15.13)
- Compared to Indigenous Australians who never smoked and were ex-smokers, a higher proportion Indigenous Australians both aged 15 years or 18 years and over who were current daily smokers were in the lowest quintile of household income and SEIFA disadvantage, did not have a non-school qualification, were currently renting; and had experienced stressors in the last 12 months (Table 2.15.14, Table 2.15.15).

NATSIHS data

Smoking prevalence data presented below are from the 2004–05 NATSIHS, with non-Indigenous comparisons from the 2004–05 National Health Survey.

- In 2004–05, approximately 46% of Indigenous Australians aged 18 years and over reported they were current daily smokers compared with 21% of non-Indigenous Australians. Around 24% of Indigenous adults were ex-smokers compared with 30% of non-Indigenous adults (Table 2.15.16).

Smoking status by age group and sex

- A higher proportion of Indigenous and non-Indigenous males were current daily smokers (48% and 24% respectively) compared with Indigenous and non-Indigenous females (45% and 18% respectively) (Table 2.15.16).
- Indigenous adults aged 25–34 and 35–44 years were most likely to report being current daily smokers (both 55%). The lowest proportion of Indigenous adults who were current daily smokers were aged 55 years and over (30%) (Table 2.15.16).

(continued)

Table 2.15.16 (continued): Smoker status, by Indigenous status, sex and age group, 2004–05

(a) Directly age-standardised proportions.
(b) Includes smoker status not known.
(c) Estimate has a relative standard error of between 25% and 50% and should be used with caution.
(d) Estimate has a relative standard error greater than 50% and is considered too unreliable for general use.

Source: ABS 2006.

Smoking status by selected population and health characteristics

Table 2.15.17 presents the proportion of Indigenous and non-Indigenous Australians aged 18 years and over, by smoking status and selected population characteristics. The table should be interpreted noting that the proportions sum to 100% across the columns for smoking status (for Indigenous and non-Indigenous). The most useful interpretation of the data presented is to compare the proportions for the two categories presented for each population characteristic (rows) within each column for smoking status for firstly Indigenous Australians, and then compare this to the data for non-Indigenous Australians.

- In 2004–05, Indigenous Australians aged 18 years and over were more likely to report being a current smoker if they were in the lowest (1st) household income quintile than if they were in the highest (55% compared with 32%); were in the most disadvantaged SEIFA (socio-economic index for areas) quintile (1st) than if they were in the least disadvantaged (52% compared with 25%); and if they were unemployed than if they were employed (76% compared with 42%). Similar trends were reported for non-Indigenous Australians (Table 2.15.17).
- Indigenous Australians were more likely to report being a current smoker if they did not have a non-school qualification than if they did (52% compared with 41%) or if the highest year of schooling completed was Year 9 or below than if they completed Year 12 (58% compared with 29%) (Table 2.15.17).
- A higher proportion of Indigenous Australians aged 18 years and over with a self-assessed health status of fair/poor reported being a current smoker than those with a self-assessed health status of excellent/very good (57% compared with 40%). Indigenous Australians were slightly more likely to report being an ex-smoker if they had diabetes than if they did not (27% compared with 22%) and if they had cancer than if they did not (29% compared with 24%). A higher proportion of Indigenous Australians without cancer reported they had never smoked (28%) than those with cancer (21%) (Table 2.15.17).
- Indigenous Australians aged 18 years and over were more likely to report being a current smoker if they drank at short- or long-term risky/high-risk levels than if they did not (long-term 66% compared with 45%, short-term 67% compared with 49%) (Table 2.15.17).
- Indigenous Australians aged 18 years and over were more likely to report being a current smoker if they reported their exercise level as low/sedentary rather than high (49% compared with 32%); if they reported not eating fruit daily (65%) compared with those who did (46%); if they reported not eating vegetables daily (56%) compared with those who did (48%); and if they were normal or underweight rather than if they were overweight or obese (57% compared with 43%) (Table 2.15.17).

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82 per cent of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on-health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS as the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may however be used to obtain rough non-Indigenous comparisons for some data items. Where possible ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

There was a relatively large level of under-coverage and caution should be exercised when interpreting the survey results. The under-identification of Indigenous persons in non-community areas is estimated to be up to 31% of those screened. This estimate is the remaining level of undercoverage when all other known sources of undercoverage have been removed. Part of this percentage is likely to be due to other factors which are unknown (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: users' guide, 2008* (ABS 2010).

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys

with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, imperfect recall or individual interpretation of survey questions may affect some responses.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner* and *Outer regional* areas, and *Remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 National Health Survey.

In remote communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

The survey included smoking status, starting age of tobacco use, Indigenous status, age and sex. The NATSIHS has a large Indigenous sample size resulting in reliable estimates.

The question on smoking is asked of persons aged 18 years and over. Since most Australians start smoking before the age of 18, this limits our understanding of teenage smoking patterns. Teenagers are one of the main groups that smoking prevention programs focus on.

List of tables

2.16 Risky alcohol consumption

The proportion of Aboriginal and Torres Strait Islander people who consume alcohol at risky or high-risk levels

Data sources

Data for this measure come from the 2004–05 National Aboriginal and Torres Strait Islander Health Survey, the 2008 National Aboriginal and Torres Strait Islander Social Survey, the National Mortality Database and the National Hospital Morbidity Database.

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS).

The NATSIHS collected information on risky and high-risk alcohol consumption, which is defined as that which exceeds the National Health and Medical Research Council (NHMRC) guidelines for low-risk drinking, in the short-term or long-term. These guidelines are outlined below.

Risky/high-risk drinking—adult males

- Short-term risky drinking for males is consumption in excess of six but less than 11 standard drinks on any one day.
- Short-term high-risk drinking for males is consumption of 11 or more standard drinks on any one day.
- Long-term risky drinking is average consumption in excess of four but less than six standard drinks per day amounting to 29 but less than 42 standard drinks per week.
- Long-term high-risk drinking is average consumption in excess of six standard drinks per day amounting to 43 or more standard drinks per week.

Risky/high-risk drinking—adult females

- Short-term risky drinking is consumption in excess of four but less than seven standard drinks on any one day.
- Short-term high-risk drinking is consumption in excess of seven or more standard drinks on any one day.

- Long-term risky drinking is average consumption in excess of two but less than five standard drinks per day amounting to 15 but less than 28 standard drinks per week.
- Long-term high-risk drinking is consumption in excess of four standard drinks per day which amounts to 29 or more standard drinks per week.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

The National Mortality Database

The National Mortality Database is a national collection of de-identified unit record level data. It comprises most of the information recorded on death registration forms and medical (cause of death) certificates, including Indigenous status. The database is maintained by the Australian Institute of Health and Welfare (AIHW). Information on the characteristics and causes of death of the deceased is provided by the Registrars of Births, Deaths and Marriages and coded nationally by the Australian Bureau of Statistics (ABS). Information on the cause of death is supplied by the medical practitioner certifying the death, or by a coroner. The data are updated each calendar year and are presented by state/territory of usual residence rather than state/territory where death occurs.

It is considered likely that most deaths of Aboriginal and Torres Strait Islander people are registered. However, a proportion of these deceased are not reported as Aboriginal or Torres Strait Islander by the family, health worker or funeral director during the death registration process. That is, while data are provided to the ABS for the Indigenous status question for 99% of all deaths, there are concerns regarding the accuracy of the data. The Indigenous status question is not always directly asked of relatives and friends of the deceased by the funeral director.

While the identification of Indigenous Australians in deaths data is incomplete in all state and territory registration systems, 5 jurisdictions (New South Wales, Queensland, Western Australia, South Australia and the Northern Territory) have been assessed by the ABS and the AIHW as having adequate identification. Longer term mortality trend data are limited to 3 jurisdictions (Western Australia, South Australia and the Northern Territory) with adequate identification of Indigenous deaths in their recording systems from 1991 onwards. The quality of the time-series data is also influenced by the late inclusion of a not stated category for Indigenous status in 1998. Prior to this time, the not stated responses were probably included with the non-Indigenous.

Deaths registered in 2010 with a usual residence of Queensland have been adjusted to exclude deaths registered in 2010 that occurred prior to 2007. This is to minimise the impact of late registration of deaths due to recent changes in the timeliness of death registrations in Queensland.

Western Australian Aboriginal and Torres Strait Islander deaths for 2007, 2008 and 2009, have been revised to correct for a data quality issue which resulted in the over-reporting of Indigenous deaths during this period.

Deaths for which the Indigenous status of the deceased was not reported have been excluded from the analysis.

Data have been combined for the 5-year period 2006–2010 because of the small number of deaths from some conditions each year. Data have been analysed using the year of registration of death for all years.

The National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

Data analyses

Age-standardised rates and ratios have been used as a measure of hospitalisations in the Indigenous population relative to other Australians. Ratios of this type illustrate differences between the rates of hospital admissions among Indigenous people and those of other Australians, taking into account differences in age distributions.

NATSIH data

The 2004–05 NATSIHS collected data on alcohol consumption based on levels of risk associated with short-term drinking (consuming alcohol at risky levels in a single day over the past 12 months) and long-term risk levels (based on average daily consumption over the previous week).

Self-reported alcohol consumption and risk levels

- In 2004–05, approximately 50% of Indigenous Australians aged 18 years and over reported having consumed alcohol in the week before the survey, and around one-quarter (24%) of Indigenous adults reported they had not consumed alcohol in the previous 12 months (Table 2.16.1).
- Of those who consumed alcohol in the week before the survey, around one-third (34%) reported drinking at long-term risky/high-risk levels (Table 2.16.1).
- Indigenous adults were twice as likely as non-Indigenous Australians to have abstained from alcohol consumption in the previous 12 months.
- Overall, based on alcohol consumption in the week before the survey, approximately 17% of Indigenous adults reported drinking at long-term risky/high-risk levels (Table 2.16.2).
- Fifty five per cent of Indigenous adults drank at short-term risky/high-risk levels in the previous 12 months and 19% drank at short-term risky/high-risk levels at least once a week in the previous 12 months (Table 2.16.2).
- After adjusting for differences in age structure, Indigenous Australians were twice as likely as non-Indigenous Australians to drink at short-term risky/high-risk levels at least once a week in the previous 12 months. However, Indigenous and non-Indigenous Australians were equally as likely to drink at long-term risky/high-risk levels in the week before the survey (about 15%).

Table 2.16.1: Alcohol consumption by Indigenous status, persons aged 18 years and over, 2004–05

	Non age-standardised proportions	Age-standardised proportions		
	Indig.	Indig.	Non-Indig.	Rate ratio
Consumed alcohol in last week	49	45	63	0.7*
Did not consume alcohol in last week	50	53	36	1.5*
Consumed alcohol in last 12 months	75	70	84	0.8*
Did not consume alcohol in last 12 months	24	29	15	1.9*

Alcohol risk levels by age

- Indigenous Australians aged 35–44 years were most likely to report drinking at long-term risky/high-risk levels in the previous week (20%) (Table 2.16.2).
- Indigenous Australians were more likely than non-Indigenous Australians to report drinking at short-term risky/high-risk levels at least once in the previous 12 months across all age groups except in the 18–24 year aged group where the levels were similar (64% and 63%, respectively).
- A significantly higher proportion of Indigenous Australians aged 25–34 and 35–44 years drank at long-term risky/high-risk levels in the previous week than non-Indigenous Australians of the same age.

Alcohol risk levels by sex

- A higher proportion of Indigenous females than Indigenous males reported abstaining from alcohol consumption in the 12 months prior to survey (30%compared with 17%) (Table 2.16.3).
- Indigenous males were more likely to report drinking at short-term and long-term risky/high-risk levels than Indigenous females.
- Indigenous males and females were two and three times as likely as non-Indigenous males and females to report drinking at short-term risky/high-risk levels at least once a week in the previous 12 months.
- Indigenous males were more likely to report drinking at long-term risky/high-risk levels in the week before the survey than non-Indigenous males (18% compared with 15%). The proportions of Indigenous and non-Indigenous females reporting drinking at long-term risky/high-risk levels were similar.

Alcohol risk levels by state/territory

- The proportion of Indigenous adults who drank at long-term risky/high-risk levels ranged from 8% in the Northern Territory to 19% in Queensland and Western Australia (Table 2.16.4).
- Indigenous Australians were more likely than non-Indigenous Australians to report drinking at short-term risky/high-risk levels at least once a week in all states and territories. The proportion of Indigenous and non-Indigenous Australians reporting drinking at long-term risky/high-risk levels in the previous week was similar across all states and territories (Table 2.16.5).

* Represents results with statistically significant differences at the $p < 0.05$ level in the Indigenous/non-Indigenous comparisons.

(a) Risk level based on Australian Alcohol Guidelines 2000.

(b) Non-Indigenous data not available for the Northern Territory because of small sample size. Northern Territory records for non-Indigenous people contribute to the national estimates but are insufficient to support reliable estimates for the Northern Territory.

(c) No alcohol consumed in previous 12 months.

(d) Estimate has a relative standard error of between 25% and 50% and should be used with caution.

(e) Based on responses to questions in 2004–05 NHS/NATSIHS about frequency of consumption of specified number of drinks in previous year. The number of drinks was based on the NHMRC guidelines for risky and high-risk short-term alcohol consumption for males and females.

(f) Persons who consumed alcohol at specified risky/high-risk levels in the short-term on at least one occasion in the previous 12 months.

(g) Persons who consumed alcohol at specified risky/high-risk levels in the short-term at least once a week in the previous 12 months.

(h) Risk level based on consumption in the week before the interview.

Source: ABS and AIHW analysis of 2004–05 NATSIHS and 2004–05 NHS.

Alcohol risk levels by remoteness

- Indigenous adults in remote areas were more likely than those in non-remote areas to report drinking at short-term risky/high-risk levels in the week before the interview. Similar proportions of Indigenous Australians in remote and non-remote areas reported drinking at long-term risky/high-risk levels in the week before the interview (15% and 17%, respectively) (Table 2.16.6).
- Indigenous adults in remote areas were much more likely to have abstained from alcohol consumption in the previous 12 months than Indigenous adults in non-remote areas (38% compared with 19%)

Table 2.16.6: Alcohol risk levels,(a) by remoteness, Indigenous persons aged 18 years and over, 2004–05

Alcohol risk levels by selected health and population characteristics

- The proportion of Indigenous Australians aged 18 years and over who drank at long-term risky/high-risk levels and reported their health as fair/poor (25%) was similar to the proportion of Indigenous Australians in the total population who reported their health as fair/poor (24%) (Table 2.16.7).
- Indigenous Australians who spoke English as their main language at home (18%) or were in the highest (4th and 5th) quintiles of household income (20%) were more likely to drink at long-term risky/high-risk levels than Indigenous Australians who spoke a language other than English as their main language (9%) or were in the lowest (1st) quintile of household income (15%) (Table 2.16.8).
- Indigenous Australians who were not in the labour force were less likely to report drinking at short-term or long-term risky/high-risk levels than Indigenous Australians who were employed or unemployed (Table 2.16.8).

NATSISS data

The 2008 NATSISS included a set of questions on chronic alcohol consumption (amount consumed on a usual drinking day in previous 12 months) and binge drinking (largest quantity of alcohol consumed in a single day during the previous fortnight). Note that these questions are not the same questions that were asked in the 2004–05 NATSIHS and therefore results are not comparable.

Indigenous persons aged 15 years and over

- In 2008, 17% of Indigenous people aged 15 years and over reported drinking at chronic risky/high-risk levels, 46%reported drinking at low risk levels and 35% had not consumed alcohol in the previous 12 months (Table 2.16.9).
- The proportion of Indigenous people aged 15 years and over who reported drinking at chronic risky/high-risk levels in 2008 (17%) was similar to the proportion reported in the 2002 NATSISS (15%) (ABS 2012).
- Indigenous males were more likely than Indigenous females to drink at chronic risky/high-risk levels (20% compared with 14%) (Table 2.16.9).

Binge drinking

- In 2008, 37% of Indigenous people age 15 years and over reported drinking at acute risky/high-risk levels (binge drinking) in the two weeks prior to the survey, this is similar to the rate reported in 2002 (ABS 2012).
- Binge drinking was more common among Indigenous males (46%) than Indigenous females (28%) (ABS 2012).

Table 2.16.9: Alcohol risk levels[(a)], Indigenous persons aged 15 years and over, by sex, 2008

Indigenous persons aged 18 years and over

- In 2008, 39% of Indigenous people aged 18 years and over reported drinking at short-term risky/high-risk levels in the two weeks prior to interview (Table 2.16.10).
- The proportion of Indigenous persons aged 18 years and over who reported drinking at short-term risky/high-risk levels decreased with age, from 49% in the 18–24 year age group to 20% for those aged 55 years and over (Table 2.16.10).

Table 2.16.10: Alcohol risk levels[(a)], Indigenous persons aged 18 years and over, 2008

Alcohol risk levels by state/territory

- The proportion of Indigenous adults who drank at short-term risky levels in the last 12 months varied across jurisdictions, from 29% in the Northern Territory to 46% in Western Australia (Table 2.16.12).
- Western Australia had the highest proportion (18%) of Indigenous adults who drank at long-term risky levels at least once a week in the last 12 months, and the Northern Territory had the lowest proportion (13%) (Table 2.16.12).

Alcohol consumption during pregnancy

Information about alcohol consumption during pregnancy is available from the 2008 NATSISS.

- In 2008, 3% of mothers of Indigenous children aged 0–3 years drank more or the same amount of alcohol during pregnancy, 16% drank less and 80% did not drink at all during their pregnancy (Table 2.16.16).
- The proportion of mothers who did not drink alcohol during pregnancy was greatest in the Northern Territory (85%), and lowest in Victoria and Queensland (77%). The proportion of mothers who drank more or the same amount of alcohol during pregnancy

was greatest in Tasmania and the Australian Capital Territory combined (6%) and lowest in South Australia and Queensland (2%) (Table 2.16.16).

Mortality

Table 2.16.10 presents deaths related to alcohol use of Indigenous Australians in New South Wales, Queensland, Western Australia, South Australia and the Northern Territory over the period 2006–2010.

- In New South Wales, Queensland, Western Australia, South Australia and the Northern Territory, there were 382 deaths of Indigenous Australians related to alcohol use (Table 2.16.17). This represented approximately 3.4% of total deaths of Indigenous Australians in these jurisdictions.
- Of all deaths related to alcohol use among Indigenous people, the majority were for alcoholic liver disease (261 deaths).
- Overall, Indigenous males died from alcohol-related causes at 5 times the rate of non-Indigenous males and Indigenous females died from alcohol-related causes at 8 times the rate of non-Indigenous females.
- Indigenous Australians died from mental and behavioural disorders due to alcohol use at 7 times the rate of non-Indigenous Australians, from alcoholic liver disease at 6 times the rate, and by alcohol poisoning at 5 times the rate.

Table 2.16.17 (continued): Deaths related to alcohol use, NSW, Qld, WA, SA and NT, 2006–2010(a)(b)(c)(d)(e)(g)

* Represents results with statistically significant differences at the $p < 0.05$ level, the Indigenous/non-Indigenous comparisons.

(a) Data are reported for New South Wales, Queensland, Western Australia, South Australia and the Northern Territory only. These five states and territories are currently considered to have adequate levels of Indigenous identification in mortality data for these periods. Data for these five jurisdictions over-represent Indigenous populations in less urbanised and more remote locations. Mortality data for the five jurisdictions should not be assumed to represent the experience in the other jurisdictions.

(b) Data are presented in 5-year groupings because of small numbers each year.

(c) Although most deaths of Indigenous Australians are registered, it is likely that some are not accurately identified as Indigenous. Therefore, these statistics are likely to underestimate the Indigenous mortality rate. It is also difficult to exactly identify the difference between the Indigenous and non-Indigenous mortality rates because of these data quality issues.

(d) Deaths prior to 2007 are by year of registration and state/territory of usual residence. Deaths from 2007 onwards are by reference year and state/territory of usual residence. Registration year prior to 2007 is equivalent to reference year from 2007 onwards.

(e) Care should be taken when interpreting mortality rates for Queensland due to recent changes in the timeliness of birth and death registrations. Queensland deaths data for 2010 have been adjusted to minimise the impact of late registration of deaths on mortality indicators.

(f) All causes of death data from 2006 onward are subject to a revisions process - once data for a reference year are 'final', they are no longer revised. Affected data in this table are: 2006 (final), 2007 (final), 2008 (final), 2009 (revised) and 2010 (preliminary). See Causes of Death, Australia, 2010 (cat.no. 3303.0) Explanatory Notes for further information.

(g) Rates are directly age-standardised death rates per 100,000, using the 2001 Australian Estimated Resident population, by 5-year age group to 75+.

(h) Rate ratio is the mortality rate for Indigenous Australians divided by the mortality rate for non-Indigenous Australians.

(i) Rate difference is the mortality rate for Indigenous Australians minus the mortality rate for non-Indigenous Australians.

(j) Rate difference per cent is the rate difference for each specific cause divided by the rate difference for deaths related to alcohol use.

(k) Rate difference per cent of all causes is the rate difference for each specific cause divided by the rate difference for all causes.

Note: Deaths with not stated age have been excluded from the calculation of rates, but included in totals. Note that the ABS pro ratas not stated age across each age group in the calculation of mortality rates. This leads to some small differences in the mortality rates as calculated by ABS and AIHW.

Source: AIHW analysis of ABS Mortality Database.

Hospitalisations

Table 2.16.18 presents hospitalisations of Indigenous and non-Indigenous Australians for principal diagnoses related to alcohol use in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, over the period July 2008 to June 2010.

- There were 7,763 hospitalisations of Indigenous Australians in the six jurisdictions combined with a principal diagnosis related to alcohol use. This represented approximately 2% of all hospitalisations of Indigenous Australians (excluding dialysis) in these jurisdictions.
- Indigenous males were hospitalised for diagnoses related to alcohol use at almost five times the rate of non-Indigenous males, and Indigenous females were hospitalised for alcohol-related conditions at almost four times the rate of non-Indigenous females.
- Over three-quarters (86%) of all hospitalisations of Indigenous Australians that were related to alcohol use had a principal diagnosis of mental and behavioural disorders due to alcohol use (6,638 hospitalisations). The most common type of mental and behavioural disorder due to alcohol use was acute intoxication, for which Indigenous Australians were hospitalised at eight times the rate of non-Indigenous Australians. Indigenous Australians were hospitalised at 8 times the rate of non-Indigenous Australians for mental and behavioural disorders due to withdrawal, and 17 times the rate of non-Indigenous Australians for psychotic disorder.
- Indigenous Australians were hospitalised for alcoholic liver disease at six times the rate of non-Indigenous Australians, and for accidental poisoning by alcohol at four times the rate of non-Indigenous Australians.

* Represents results with statistically significant differences at the $p < 0.05$ level.

(a) Data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification in Health 2010).

(c) Financial year reporting.

(d) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(e) Directly age-standardised using the Australian 2001 standard population.

(f) Rate ratio Indigenous: non-Indigenous.

(g) Rate difference Indigenous minus non-Indigenous.

(h) Includes amnesic syndrome, residual or late onset psychotic disorder, other and unspecified mental and behavioural disorders due to alcohol use.

Notes

1. Rates for Indigenous are calculated using population estimates based on the 2006 Census (SERIES B).
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by remoteness

Hospitalisation rates for hospitalisations with a primary diagnosis related to alcohol use in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory are presented by Australian Standard Geographical Classification (ASGC) in Table 2.16.19, covering the period July 2008 to June 2010.

- Indigenous Australians in all remoteness areas were more likely to be hospitalised for alcohol related conditions than non-Indigenous Australians. The ratio of hospitalisations of Indigenous people compared with non-Indigenous Australians was higher and the difference was statistically significant for all ASGC areas.
- Rates of hospitalisations per 1,000 head of population were highest for Indigenous people living in *Remote* areas, at 14 per 1,000. The rate was highest for non-Indigenous Australians who lived in *Major cities*, at 2.6 per 1,000. The lowest rates were observed in *Very remote* areas for Indigenous people (6.9 per 1,000) and *Outer regional* for non-Indigenous Australians (1.6 per 1,000).
- Indigenous people were hospitalised for alcohol related conditions at a rate of 7.9 times that of non-Indigenous Australians in *Remote* areas of Australia. In *Major cities*, where the lowest ratio was observed, Indigenous Australians were hospitalised at a rate of 3.5 times that of non-Indigenous Australians. Nationally, the rate ratio was 4.1.

Table 2.16.19: Hospitalisations with a principal diagnosis related to alcohol use, by Indigenous status and remoteness, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010[(a)(b)(c)(d)(e)(f)]

	Indigenous				Non-Indigenous					
	Number	No. per 1,000	LCL 95%[(g)]	UCL 95%[(h)]	Number	No. per 1,000	LCL 95%[(g)]	UCL 95%[(h)]	Ratio[(i)]	Difference[(j)]
Major cities	2,392	9.1	8.7	9.5	75,869	2.6	2.5	2.6	3.5*	6.5*

Total[(m)]	**7,763**	**9.4**	**9.1**	**9.6**	**97,218**	**2.3**	**2.3**	**2.3**	**4.1***	**7.1***

* Indicates a significant difference at the p <0.05 level.

(a) Data are from public and most private hospitals. Data exclude private hospitals in the Northern Territory, the Australian Capital Territory and Tasmania.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification in Health 2010).

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised.

(e) Directly age-standardised using the Australian 2001 standard population, by 5 year age groups to 65+.

(f) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(g) LCL = lower confidence limit.

(h) UCL = upper confidence limit.

(i) Rate ratio Indigenous: non-Indigenous Australians.

(j) Rate difference Indigenous- non-Indigenous.

(k) Includes remote Victoria.

(l) Excludes remote Victoria.

(m) Total includes hospitalisations where ASGC is missing.

Notes

1. Rates are calculated using the remoteness distribution by Indigenous status, age and sex based on the 2006 ERP and applied to the 2008–10 population projections (Series B) based on the 2006 Census.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Data quality issues

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, imperfect recall or individual interpretation of survey questions may affect some responses.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors

Care has been taken to ensure that the results of this survey are as accurate as possible. All interviews were conducted by trained ABS officers. However, some factor may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010a).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010a).

Mortality data

Mortality data presented in this report are from the AIHW National Mortality Database. The AIHW National Mortality Database includes information on the factors that caused death, as well as other information about the deceased person, such as age at death, place of death, country of birth, and where applicable, the circumstances of their death. These data are collected in Australia by the Registrars of Births, Deaths and Marriages in each state and territory. The data are then compiled nationally by the ABS, which codes the data according to the International Classification of Diseases (ICD).

Deaths

Although it is considered likely that most deaths of Aboriginal and Torres Strait Islander (Indigenous) Australians are registered, a proportion of these deaths are not registered as Indigenous. Information about the deceased is supplied by a relative or other person acquainted with the deceased, or by an official of the institution where the death occurred and may differ from the self-identified Indigenous origin of the deceased.

Queensland deaths

In November 2010, the Queensland Registrar of Births, Deaths and Marriages advised the ABS of an outstanding deaths registration initiative undertaken by the Registry. This initiative resulted in the November 2010 registration of 374 previously unregistered deaths which occurred between 1992 and 2006 (including a few for which a date of death was unknown). Of these, around three-quarters (284) were deaths of Aboriginal and Torres Strait Islander Australians.

The ABS discussed different methods of adjustment of Queensland death registrations data for 2010 with key stakeholders. Following the discussion, a decision was made by the ABS and key stakeholders to use an adjustment method that added together deaths registered in 2010 for usual residents of Queensland which occurred in 2007, 2008, 2009 and 2010. This method minimises the impact on mortality indicators used in various government reports. However, care should still be taken when interpreting Aboriginal and Torres Strait Islander death data for Queensland for 2010.

Western Australia deaths

Indigenous deaths registered in Western Australia in 2007, 2008 and 2009 were corrected by the ABS in mid-2012 due to some non-Indigenous deaths being incorrectly recorded as Indigenous for these years. Data presented in this report are based on the corrected data and will differ from mortality data presented in the 2010 Health Performance Framework report which presented data prior to the ABS corrections.

Indigenous status question

All jurisdictions comply with the standard wording for the Indigenous status question and categories for their death registration forms.

Under-identification

At present, there is considerable variation across the states and territories in the completeness of mortality data for Indigenous people. Information concerning the number of deaths of Indigenous people is limited by the accuracy with which Indigenous persons are identified in death records. Problems associated with identification result in an underestimation of deaths of Indigenous people and in the gap in mortality between Indigenous and non-Indigenous Australians.

Mortality data for New South Wales, Queensland, Western Australia, South Australia and the Northern Territory are considered to have sufficient coverage to produce reliable statistics on Indigenous Australian deaths for the period 2001–2010.

Longer term mortality trend data are limited to three jurisdictions (Western Australia, South Australia and the Northern Territory) which are considered to have adequate identification from 1991. Queensland is considered to have sufficient coverage of Indigenous deaths from 1998.

The quality of the time series data is also influenced by the late inclusion of a ‘not stated’ category for Indigenous status in 1998. Before this time, the ‘not stated’ responses were probably included with the non-Indigenous.

Note that different causes may have levels of under-identification that differ from the all-cause coverage estimates. Note also that the quality of the cause of death data depends on every step of the process of recording and registering deaths (including the documentation available at each step of the process) from certification to coding of cause of death.

Indigenous Mortality Quality Study

The ABS conducted a number of quality studies based on the 2006 Census of Population and Housing and other data sets as part of the Census Data Enhancement (CDE) project (ABS 2008). The CDE Indigenous Mortality Quality Study linked Census records with death registration records for the 11-month period following the Census and examined differences in the reporting of Indigenous status across the two data sets.

For the purpose of this study, the linked record was assumed to be an Indigenous record if a positive response was recorded against the Indigenous status question on either the death registration or the corresponding Census record. Following linkage, the number of death records identified as Indigenous increased from 1,800 to 2,123 records, or from 1.7% to 2.0% of all registered deaths.

‘While 323 additional death records were able to be identified as Indigenous from Census records, more may have been expected if all death records had been linked. A key reason records could not be linked appears to be Census undercount, with a corresponding Census record not existing to link to for many Indigenous death records’ (ABS 2008).

The results from the study suggested that coverage of Indigenous deaths in death registrations is considerably higher, at least in 2006–07, than previous estimates have indicated. Nationally, the coverage rate was estimated to be 85%. State/territory coverage estimates were: NSW 76%, Vic 74%, Qld 87%, SA 86%, WA 92% and NT 99% (ABS 2008).

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in death records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used here are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories.

Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

2.17 Drug and other substance use including inhalants

The use of drugs and other substances including inhalants among Aboriginal and Torres Strait Islander people

Data sources

Data for this measure come from the 2008 National Aboriginal and Torres Strait Islander Social Survey, the National Hospital Morbidity Database and the Australian Institute of Criminology Drug Use Monitoring in Australia (DUMA) survey.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

Drug Use Monitoring in Australia (DUMA) survey

DUMA is an annual survey which has been conducted by the AIC since 1999 at some locations across Australia. The survey reports on drug use among police detainees at selected police stations. The survey is by a voluntary questionnaire and drug use is confirmed by a urine sample provided by the detainee.

The number of detainees questioned is quite low and thus includes a very small Indigenous sample. The Indigenous status of the detainee is established by the following question: 'What is your ethnic background?' (if the respondent mentions 'Australian' but not 'Aboriginal', prompt: 'Do you consider yourself an Aboriginal or Torres Strait Islander?').

Analysis is presented by state/territory, as the figures do not permit national coverage.

Data analyses

Age-standardised rates and ratios have been used as a measure of morbidity in the Indigenous population relative to other Australians. Ratios of this type illustrate differences between the rates of morbidity among Indigenous people and those of other Australians, taking into account differences in age distributions.

Illicit substance use can be divided into two categories: use of substances which are illegal to possess (for example, heroin) and non-medical use of substances that are legally available (for example, petrol inhalation and misuse of prescription drugs).

Self-reported illicit drug use

Self-reported data on illicit substance use among the Aboriginal and Torres Strait Islander population from the 2008 and 2002 NATSISS are presented below.

- In 2008, approximately 23% of Indigenous Australians aged 15 years and over reported illicit substance use in the 12 months before the survey (Table 2.17.1).
- In 2008, 43% of Indigenous persons aged 15 years and over reported illicit substance use at least once in their lifetime (Table 2.17.2).

Substance use by age and sex

- In 2008, the age groups with the highest proportions of Indigenous persons who used substances in the previous 12 months were aged 18–24 years (32%) and 25–34 years (26%) (Table 2.17.1).
- In 2008, 51% of Indigenous males and 36% of Indigenous females aged 15 years and over reported illicit substance use at least once in their lifetime (Table 2.17.2).

Substance use by remoteness

- In 2008, a higher proportion of Indigenous persons aged 15 years and over in non-remote areas than remote areas reported ever having used illicit substances (47% compared with 31%) and substance use in the previous 12 months (24% compared with 17%) (Table 2.17.3).

Type of substance use

- Marijuana was the most commonly reported illicit drug used by Indigenous Australians aged 15 years and over in 2008. Around 36% reported ever having tried marijuana and 17% had used marijuana in the previous 12 months. Amphetamines/speed was the next most frequently reported substance ever used (11%) while ecstasy and designer drugs followed (8%) (Table 2.17.4).

Table 2.17.4: Illicit substance use, Indigenous persons aged 15 years and over, 2008

	Ever used	Used in last 12 months
	Per cent	
Marijuana, hashish or cannabis	35.9	17.2
Amphetamines/speed	10.9	4.0
Painkillers/analgesics	7.4	4.5
LSD/synthetic hallucinogens	5.2	0.9
Ecstasy/designer drugs	7.7	3.3

Time series analyses

- For Indigenous people aged 15 years and over who accepted the substance use form, reported rates of ever having used illicit substances increased slightly from 40% to 43% between 2002 and 2008 (Table 2.17.5).
- Over the same period, reported rates of illicit substance use in the 12 months before the survey were similar (24% in 2002 and 23% in 2008).
- The proportion of Indigenous Australians who reported marijuana, hashish or cannabis resin use in the previous 12 months decreased from 2002 to 2008 (19% compared with 17%).
- The proportion of Indigenous males who reported use of amphetamines/speed in the last 12 months in 2008 was similar to that reported in 2002 (around 5%).

(a) People who accepted the substance use form.

(b) Estimates with a relative standard error of between 25% and 50% should be used with caution.

(c) Estimates with a relative standard error greater than 50% are considered too unreliable for general use.

(d) Includes other analgesics and heroin.

(e) Includes petrol, volatile solvents and other inhalants.

Source: AIHW and ABS analysis of 2002 and 2008 NATSISS.

Substance use by selected health and population characteristics

Tables 2.17.6 and 2.17.7 present information on Indigenous persons aged 15 years and over, by substance use status and selected health and population characteristics. Proportions in Table 2.17.6 are calculated within a column using the total across the rows as a denominator; while proportions in Table 2.17.7 are calculated within a row using the column totals as a denominator.

- In 2008, a higher proportion of Indigenous persons aged 15 years and over who were recent substance users (that is, used substances in the previous 12 months) reported they were currently daily smokers than those who had never used illicit substances (Table 2.17.6).
- Indigenous persons who were recent substance users were also more likely to be unemployed, renters and have experienced stressors in the last 12 months than persons who had never used illicit substances (Table 2.17.6).
- A higher proportion of Indigenous persons with high/very high levels of psychological distress had ever used substances, than Indigenous persons with low/moderate levels of psychological distress (50% compared with 40%) (Table 2.17.7).
- Interestingly, Indigenous persons in the highest quintiles of household income were more likely to have ever used substances that Indigenous persons in the lowest income quintiles (Table 2.17.7).

Table 2.17.6: Substance use status, by selected health and population characteristics, Indigenous persons aged 15 years and over[(a)(b)], 2008

Multiple drug use

- In 2008, approximately 19% of Indigenous males and 13% of Indigenous females aged 15 years and over had used one substance in the previous 12 months, and 9% of Indigenous males and 4% of Indigenous females had used two or more substances in the previous 12 months (Table 2.17.8).
- Use of multiple substances among Indigenous Australians ranged from 13% among those who drank alcohol at risky/high risk levels, to 9% among current smokers and 8% among those who had high or very high levels of psychological distress (Table 2.17.9).
- In 2008, Indigenous Australians who consumed alcohol at risky or high risk levels, or who were current smokers, where around 3.5 times more likely than those who did not drink at risky levels or smoke to report multiple substance use. Indigenous Australians who reported high levels of psychological distress were almost 2 times more likely than those with low or moderate levels to report multiple substance use. These differences were statistically significant (Table 2.17.9).

Substance use during pregnancy

Data on the use of illicit drugs or substances by the mothers of Indigenous children aged 0–3 years during pregnancy from the 2008 NATSISS is presented in Table 2.17.10 and Table 2.17.11. Rates by state/territory are presented in Table 2.17.10 and rates by Australian Standard Geographical Classification (ASGC) are presented in Table 2.17.11. For further information on substance use during pregnancy see indicator '2.21 Health behaviours during pregnancy'.

- In 2008, 5% of mothers of Indigenous children aged 0–3 years reported that they used illicit substances during pregnancy.
- Use of illicit drugs or substances during pregnancy by the mothers of Indigenous children aged 0–3 years was highest in Victoria and Western Australian (9%) (Table 2.17.10).
- Use of illicit drugs or substances during pregnancy by the mothers of Indigenous children aged 0–3 years was similar in remote and non-remote areas (5%) (Table 2.17.11).

Hospitalisations

Table 2.17.12 presents data on hospitalisations with principal diagnoses related to drug use for the period July 2008 to June 2010 in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory.

- During the period July 2008 to June 2010, in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined there were 4,537 hospitalisations of Indigenous Australians relating to substance use (Table 2.17.12).
- Indigenous Australians were hospitalised for conditions relating to substance use at around twice the rate of non-Indigenous Australians.
- Poisoning due to anti-epileptic, sedative-hypnotic and anti-Parkinson disease drugs, poisoning due to psychotropic drugs, and poisoning due to antibiotics and hormones were responsible for 14%, 15% and 13% respectively of all hospitalisations of Indigenous Australians relating to substance use over the period June 2008 to July 2010. Indigenous Australians were hospitalised for these three types of poisoning at almost twice the rate of non-Indigenous Australians.
- Mental and behavioural disorders due to use of cannabis and use of multiple drug and psychoactive substances were responsible for 17% and 9% respectively of all hospitalisations of Indigenous Australians relating to substance use. Indigenous Australians were hospitalised for these disorders at five and three times the rate of non-Indigenous Australians respectively.

Table 2.17.13 presents hospitalisations for external causes related to drug use for the period July 2008 to June 2010 in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory.

- Indigenous Australians were hospitalised for external causes related to drug use at 4.3 per 1,000 population, while the rate for non-Indigenous Australians was 1.9 per 1,000 population (Table 2.17.13).

Hospitalisations by remoteness

Hospitalisation rates with a principal diagnosis related to drug use in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory covering the period July 2008 to June 2010 are presented by Australian Standard Geographical Classification (ASGC) in Table 2.17.14.

- Indigenous Australians were more likely to be hospitalised for drug related conditions than non-Indigenous Australians for all remoteness classifications. There was a statistically significant difference between the rate of hospitalisation of Indigenous Australians and non-Indigenous Australians in all remoteness areas.
- Rates of hospitalisation were highest for Indigenous Australians in *Major cities* (5.8 per 1,000 population), followed by *Inner regional* (4.7 per 1,000), *Remote* (4.1 per 1,000*), Outer regional* (3.6 per 1,000) and *Very remote* areas (1.9 per 1,000). For non-Indigenous Australians, rates were highest in *Major cities* and *Inner regional* areas (1.9 per 1,000), followed by *Outer regional* (1.7 per 1,000), remote (1.5 per 1,000) and *Very remote* areas (1.3 per 1,000).
- Indigenous Australians were three times more likely than non-Indigenous Australians to be hospitalised for drug related conditions in *Major cities* of Australia. In *Very remote* areas, where the lowest rate ratio was observed, Indigenous Australians were 1.4 times more likely than non-Indigenous Australians to be hospitalised.

Table 2.17.14: Hospitalisations with a principal diagnosis related to drug use, by Indigenous status and remoteness, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010(a)(b)(c)(d)(e)(f)

(a) Data are from public and most private hospitals. Data exclude private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification of Health 2010).

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised.

(e) Directly age-standardised using the Australian 2001 standard population, by 5 year age groups to 65+.

(f) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(g) LCL = lower confidence limit.

(h) UCL = upper confidence limit.

(i) Rate ratio Indigenous: non-Indigenous.

(j) Rate difference Indigenous- non-Indigenous.

(k) Includes remote Victoria.

(l) Excludes remote Victoria.

(m) Total includes hospitalisations where ASGC is missing.

Notes

1. Rates are calculated using the remoteness distribution by Indigenous status, age and sex based on the 2006 ERP and applied to the 2008-10 population projections (Series B) based on the 2006 Census.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisation rates for external causes related to drug use in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory are presented by Australian Standard Geographical Classification (ASGC) in Table 2.17.15, covering the period July 2008 to June 2010.

- Indigenous Australians in all remoteness areas, except *Very remote*, were more likely to be hospitalised for these conditions than non-Indigenous Australians. There was a statistically significant difference between the rate of hospitalisations of Indigenous Australians and the rate of hospitalisations of non-Indigenous Australians in all ASGC areas, except *Very remote*.
- Rates of hospitalisations per 1,000 head of population were highest for Indigenous people living in *Major cities*, at 0.8 per 1,000. The rate was highest for non-Indigenous Australians who lived in *Very remote* areas, at 0.5 per 1,000. The lowest rates were observed in *Very remote* areas for Indigenous people (0.4 per 1,000) and *Major cities* for non-Indigenous Australians (less than 0.3 per 1,000).
- Indigenous people were hospitalised for these conditions at 2.6 times the rate of non-Indigenous Australians in *Major cities* of Australia. In *Very remote* areas, where the lowest

rate ratio was observed, Indigenous Australians were hospitalised at around the same rate as non-Indigenous Australians.

Table 2.17.15: Hospitalisations for any external causes related to drug use, by Indigenous status and remoteness, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010(a)(b)(c)(d)(e)(f)

Detainees and drug use

The AIC Drug Use Monitoring in Australia (DUMA) survey reports on drug use among police detainees at selected police stations in Australia. The survey is by a voluntary questionnaire and drug use is confirmed by a urine sample provided by the detainee. Data from the 2010 and 2011 surveys are presented in Tables 2.17.16 and 2.17.17.

Data from 2010 DUMA survey

- In 2010, in all of the selected police stations shown in Table 2.17.16 there was a higher proportion of Indigenous detainees testing positive to drugs than non-Indigenous detainees.
- Between 57% and 100% of Indigenous detainees at selected police stations in South Australia, New South Wales, Queensland, Western Australia, the Northern Territory and

Victoria tested positive to drugs in 2010 compared with between 54% and 70% of non-Indigenous detainees.

- Cannabis was the most common drug for which both Indigenous and non-Indigenous detainees tested positive. Methamphetamines and benzodiazepines were also common drugs to which Indigenous and non-Indigenous detainees tested positive. Between 3% and 55% of Indigenous detainees and between 2% and 29% of non-Indigenous detainees tested positive for multiple drugs.

Data from 2011 DUMA survey

Data from the 2011 DUMA survey is presented in table 2.17.16. Please note that this data only became available after the 2012 Aboriginal and Torres Strait Islander Health Performance Framework was published by the Department of Health and Ageing.

- In 2011, in all of the selected police stations shown in Table 2.17.17 there was a higher proportion of Indigenous detainees testing positive to drugs than non-Indigenous detainees.
- Between 70% and 100% of Indigenous detainees at selected police stations in South Australia, New South Wales, Queensland, Western Australia, the Northern Territory and Victoria tested positive to drugs compared with between 52% and 71% of non-Indigenous detainees.
- Cannabis was the most common drug for which both Indigenous and non-Indigenous detainees tested positive. Methamphetamines and benzodiazepines were also common drugs to which Indigenous and non-Indigenous detainees tested positive. Between 4.4% and 40.0% of Indigenous detainees and between 2.1% and 23.9% of non-Indigenous detainees tested positive for multiple drugs.

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: User's guide, 2008* (ABS 2010).

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

AIC Drug Use Monitoring in Australia (DUMA)

The Indigenous status of the detainee is established in the questionnaire by the following question:

'What is your ethnic background?' (if the respondent mentions 'Australian' but not 'Aboriginal' prompt: 'Do you consider yourself an Aboriginal or Torres Strait Islander?').

It is likely that this question will underestimate the number of Indigenous persons being detained through a reluctance on the part of detainees to identify as Indigenous.

This survey is conducted at police stations in selected metropolitan areas and does not provide regional coverage. In addition, the actual number of detainees questioned is quite low, which does not permit great analysis of the Indigenous data. Finally, the figures do not permit national coverage, but instead analysis by state is recommended.

List of tables

2.18 Physical activity

The proportion of the Aboriginal and Torres Strait Islander adult population classified as having sedentary, low, moderate or high physical activity levels

Data sources

Data for this measure come from the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) and the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS).

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Data analyses

Physical activity

Information on the level of physical activity of Indigenous and non-Indigenous Australians aged 15 years and over in the 2 weeks before the survey was collected in non-remote areas only and is presented below.

- In 2004–05, approximately 47% of Indigenous persons reported their exercise level as sedentary, 28% as low, 18% as moderate and 7% as high.
- After adjusting for differences in age structure, approximately 51% reported their exercise level as sedentary (very low or no exercise), 27% as low and 21% as moderate or high, compared with 33%, 36% and 31% respectively of non-Indigenous Australians (Table 2.18.1).

Physical activity by age and sex

- Sedentary or low levels of physical activity were highest among Indigenous people aged 45–54 years and 55 years and over (83% and 85% respectively); moderate or high levels of physical activity were highest among those aged 15–24 and 25–34 years (32% and 27% respectively) (Table 2.18.1).
- A higher proportion of Indigenous females than Indigenous males reported that their level of exercise was sedentary (51% compared with 42%).
- A higher proportion of males exercised at moderate or high levels than females across all age groups in both the Indigenous and non-Indigenous populations.

Physical activity by state/territory

- Sedentary or low levels of physical activity among Indigenous Australians aged 15 years and over ranged from 70% in Tasmania to 78% in New South Wales (Table 2.18.2).
- A higher proportion of Indigenous Australians than non-Indigenous Australians reported their exercise level as sedentary in all states and territories. Data were not available for non-Indigenous Australians in the Northern Territory (Table 2.18.3).

Physical activity by selected health characteristics

- Approximately 58% of Indigenous Australians in non-remote areas with fair/poor health status reported exercising at sedentary levels compared with 48% of Indigenous Australians with excellent/very good/good health status (Table 2.18.4). Over three-quarters (78%) of Indigenous people aged 15 years and over who were overweight or obese reported exercising at low or sedentary levels. Approximately 79% of Indigenous Australians with a long-term health condition reported sedentary or low levels of physical activity.
- Approximately 59% of Indigenous Australians aged 18 years and over in non-remote areas who were current smokers reported sedentary levels of physical activity, compared with 45% of Indigenous Australians who never smoked (Table 2.18.5).
- Approximately one third of Indigenous Australians aged 15 years and over who completed Year 12 reported to be physically inactive in 2004–05, compared with 61% of Indigenous Australians whose highest year of schooling was Year 9 or below (Table 2.18.6)

Time series analyses

- The level of sedentary physical activity for Indigenous Australians aged 15 years and over increased between 2001 and 2004–05 from 37% to 47%. The level of low and moderate physical activity declined over the period (from 57% in 2001 to 46% in 2004–05), and the level of high physical activity remained the same (7%) (Table 2.18.7).
- After adjusting for differences in age structure, the disparity between Indigenous and non-Indigenous Australians in the proportion reporting sedentary levels of exercise was larger in 2004–05 than in 2001 (Table 2.18.7).

Table 2.18.7: Level of physical activity, persons aged 15 years and over, by Indigenous status, non-remote areas, age standardised proportions, 2001 and 2004–05

Physical activity in Indigenous children

Data on the level of physical activity in Indigenous children aged 4–14 years are presented in Tables 2.18.8, 2.18.9 and 2.18.10 for 2008.

- During 2008, 74% of Indigenous children aged 4–14 years were physically active for at least 60 minutes every day in the week before the survey. Only 3% of Indigenous children aged 4–14 years were not active at all in the previous week (Table 2.18.8).
- Western Australia and Tasmania had the highest percentage of Indigenous children aged 4–14 years who participated in any level of physical activity everyday (80% for both) and the Australian Capital Territory had the lowest (59%) (Table 2.18.9).
- The proportion of Indigenous children aged 4–14 years who were active every day for at least 60 minutes increased with remoteness, with the highest proportion in very remote areas (88%) and the lowest in Major cities (66%) (Table 2.18.10).

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: User's guide 2008* (ABS 2010).

Physical activity data

The information is 'as reported' by respondents and reflects their perception of the activity undertaken, the intensity of their participation, their level of fitness, and so on. Information about physical activity that persons aged 15 to 17 years undertook was reported by an adult within the household, usually a parent. The child may or may not have been consulted. As a result, data for this age group should be interpreted with particular care.

In general, the use of a 2-week reference period was not considered to pose significant recall problems for respondents. For many people, participation in exercise is regular and/or for a set period each session. However, to the extent that persons undertook exercise in less formal circumstances or that the reference period was atypical of usual exercise patterns, the accuracy of the information provided may have been affected.

Recent developments in the area of statistics on exercise or physical activity have tended to move away from the use of metabolic equivalent level (MET) values in deriving exercise level, and have placed more emphasis on measures of time spent exercising. Retention of the exercise level approach as described above was mainly for the purpose of consistency and comparability with data from the 1995 and 2001 National Health Surveys. However, measures of time exercising are also available as outputs from this survey (ABS 2005).

Survey respondents are required to recall recent activity in minutes without being primed and without independent checks. Diary recording (as used in the ABS Time Use Survey) or independent observation would probably produce higher quality data; however, these are more resource-intensive.

Respondents are required to provide an estimate of time spent on certain types of activity. Many come up with a broad rounded estimate or guess. Others attempt to add together in their heads the time spent in each exercise session, possibly for several different activities.

The differences of intensity between different activities is not always clear for respondents, although explanatory instructions are included. Mutual exclusivity of concepts remains a problem.

A well-recognised reporting issue for self-report surveys is the tendency of respondents to report in a socially desirable way. For example, the less active may want to over-report activity to appear healthier.

Survey questions about duration of exercise differ slightly in the questionnaire for remote areas and may affect the comparability of results.

Despite the limitations of the survey data, users have generally considered the data produced to be of sufficient quality for the very broad measures of physical activity required (ABS 2005).

A reliable tool for measuring Aboriginal and Torres Strait Islander physical activity levels has not yet been developed. A study to determine the reliability of the Active Australian Survey in measuring Aboriginal and Torres Strait Islander populations revealed that it was not a reliable tool (not culturally appropriate)(Marshall & Miller 2004). The Active Australian Survey uses very similar questions to the National Health Survey to determine physical activity levels. For this reason the data should be interpreted cautiously.

List of tables

2.19 Dietary behaviour

The dietary behaviour of Aboriginal and Torres Strait Islander people, including fruit and vegetable consumption, type of milk consumed and salt intake

Data sources

Data for this measure comes from the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS), and the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS). The Australian Guide to Healthy Eating (Kellet et al. 1998) has been used to provide guidelines on recommended daily fruit and vegetable intake for children and adolescents.

The Australian Guide to Healthy Eating

This booklet has been developed for the Australian Government Department of Health and Ageing and is based on research on nutrition. The Guide contains advice about the amounts and kinds of food to be eaten each day to maintain good health and well-being.

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including

family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Data analyses

Current guidelines according to the Australian Guide to Healthy Eating recommend daily intake of fruit and vegetables for children and adolescents as seen in Table 2.19.1. It is advised that children should eat a variety of fruit and vegetables daily: the quantities are dependent on their age, appetite, the composition of the remainder of their diet, and activity levels.

Table 2.19.1: Fruit and vegetable servings from the Australian Guide to Healthy Eating suggested for children and adolescents

	Fruit (serves)	Vegetable (serves)
4–7 years	1–2	2–4
8–11 years	1–2	3–5
12–18 years	3–4	4–9

Note: One serve of fruit is 150 grams; one serve of vegetables is 75 grams.

Source: Kellet et al. 1998.

Previous regulations stipulated that children should aim to consume a set number of serves of fruit or vegetables, the most widely quoted figures being two or more serves of fruit and five or more serves of vegetables daily regardless of their age and dietary composition.

Because of the variety of recommendations currently available, fruit and vegetable consumption as reported in this indicator is presented in terms of the number of serves consumed daily, allowing the reader to interpret the results according to whichever fruit and vegetable consumption guidelines they are familiar with.

Dietary habits

- In 2004–05, the majority of Indigenous people aged 12 years and over reported eating vegetables (95%) and/or fruit (87%) daily (Table 2.19.2).
- After adjusting for differences in age structure between the Indigenous and non-Indigenous populations, Indigenous persons aged 12 years and over were twice as likely to report no usual daily fruit consumption and seven times as likely to report no usual daily vegetable consumption as non-Indigenous persons of the same age (Table 2.19.2).
- Around 22% of Indigenous people aged 15 years and over in non-remote areas reported they sometimes added salt after cooking, and a further 44% reported they usually added salt after cooking (Table 2.19.3).
- Approximately 71% of Indigenous people aged 12 years and over in non-remote areas reported they usually drank whole (full-cream) milk and 17% reported drinking low or reduced fat milk (Table 2.19.3).
- After adjusting for differences in age structure, Indigenous Australians aged 12 years and over in non-remote areas were twice as likely to report no usual daily fruit intake, and 1.6 times as likely to report no usual daily vegetable intake. In addition, they were

more likely to consume whole milk and less likely to consume low or reduced fat milk (Table 2.19.3).

Dietary habits by age group

- In non-remote areas, Indigenous Australians aged 35–44 years were most likely to report a daily intake of five or more serves of vegetables (13%) and Indigenous Australians aged 55 years and over were most likely to report a daily fruit intake of two serves or more (Table 2.19.3).
- Indigenous and non-Indigenous people aged 12–14 years were more likely to report drinking whole milk (88% and 69%, respectively) than those in the older age groups (Table 2.19.3).
- The proportion of Indigenous people who reported usually adding salt after cooking increased with age (Table 2.19.3).

Table 2.19.2: Age standardised proportion[(a)] of usual daily vegetable consumption and usual daily fruit consumption status of persons aged 12 years and over, Australia 2004–05

	Indigenous	Non-Indigenous	Ratio
	Per cent		
Does eat vegetables on a daily basis	94.7	99.2	1.0
Does eat fruits on a daily basis	86.8	93.4	0.9
Does not eat vegetables daily	5.3	0.8	6.8
Does not eat fruit daily	13.2	6.6	2.0

(a) Proportions are directly age standardised to the 2001 Australian standard population.

(d) Includes usual type of milk not known.

Source: ABS and AIHW analysis 2004–05 NATSIHS and 2004–05 NHS.

Dietary habits by sex

- A higher proportion of Indigenous males aged 12 years and over reported not eating fruit daily than Indigenous females (16% compared with 12%) (Table 2.19.4).
- Indigenous females aged 15 years and over in non-remote areas were nearly twice as likely as Indigenous males to report drinking skim milk as the usual type of milk consumed (7% compared with 4%) (Table 2.19.5).
- There was little difference in the proportion of Indigenous males and females reporting eating vegetables daily or adding salt after cooking.

Dietary habits by state/territory

The dietary habits of Indigenous Australians aged 15 years and over in non-remote areas in 2004–05 are presented in Table 2.19.6 below, with non-Indigenous comparisons presented in Table2.19.7. Note that data on the number of daily serves of vegetables and fruit are presented for New South Wales, Victoria, Queensland and Western Australia only because of output restrictions for these data items.

- In 2004–05, the proportion of Indigenous Australians aged 15 years and over in non-remote areas who reported eating five serves or more of vegetables daily was 8% in New South Wales, 9% in Queensland, 12% in Victoria and 14% in Western Australia (Table 2.19.6).
- The proportion of Indigenous Australians aged 15 years and over reporting eating two or more serves of fruit a day was 41% in New South Wales and Queensland, 43% in Victoria and 45% in Western Australia.
- The proportion of Indigenous persons reporting drinking whole milk as the usual type of milk consumed was highest in Queensland (80%) and lowest in Victoria (62%).
- The proportion of Indigenous persons reporting usually adding salt after cooking was highest in Western Australia (57%) and lowest in Victoria (35%).
- Non-Indigenous Australians were more likely to report eating five or more serves of vegetables a day than Indigenous Australians in New South Wales, Queensland and Western Australia. Rates were similar for Indigenous and non-Indigenous Australians in Victoria (Table 2.19.7).
- Non-Indigenous Australians were more likely than Indigenous Australians to report eating five or more serves of fruit a day in three of the four jurisdictions for which data are presented (New South Wales, Victoria and Queensland) (Table 2.19.7).
- Indigenous Australians were more likely to report whole milk as the usual type of milk consumed in the four jurisdictions for which data are presented.

Dietary habits by remoteness

- Fruit and vegetables may be less accessible to Indigenous people in remote areas. In remote areas in 2004–5, 20% of Indigenous Australians aged 12 years and over reported no usual daily fruit intake compared with 12% in non-remote areas. The disparity was even greater for vegetables, where 15% of Indigenous people in remote areas reported no usual daily intake compared with 2% in non-remote areas (Table 2.19.8).
- Indigenous people in remote areas were more likely to report drinking whole milk (87%) than those in non-remote areas (76%).
- Indigenous people in remote areas were more likely than those in non-remote areas to report sometimes or usually adding salt after cooking (83% compared with 66%) (Table 2.19.8).

Time series analyses

- In 2004–05, approximately 24% of Indigenous Australians aged 12 years and over in non-remote areas reported a low usual daily vegetable intake (one or less serves per day) compared with 18% in 2001 (ABS 2002). The proportion reporting a low usual daily fruit intake (one or less serves per day) was similar in 2001 and 2004–05 (56% and 58%, respectively) (Table 2.19.9).

Table 2.19.9: Proportion of Indigenous Australians aged 12 years and over reporting high and low usual daily intake of vegetables and fruit, non-remote areas, 2001 and 2004–05

	2001	2004–05
	Per cent	
Five or more serves of vegetables (high intake)	n.a.	10.2
Two or more serves of fruit (high intake)	43.8	42.3
One or less serves of vegetables (low intake)	18.2	24.2
One or less serves of fruit (low intake)	56.2	57.5

Fruit and vegetable intake by selected health and population characteristics

- In 2004–05, a higher proportion of Indigenous Australians with fair/poor health reported no usual daily vegetable intake and/or no usual daily fruit intake than those with excellent/very good health status (Table 2.19.10).
- Indigenous Australians aged 15 years and over in the lowest (1st) quintile of household income were much more likely than those in the highest quintile to report no usual daily fruit and/or vegetable intake.
- Indigenous Australians who reported Year 9 or below as their highest year of school completed or did not have a non-school qualification were more likely to report no usual daily fruit and/or vegetable intake than those whose highest year of school completed was Year 12 or who had a non-school qualification.
- A higher proportion of Indigenous people who were renting reported no usual daily vegetable intake (7%) and no usual daily fruit intake (16%) than those who were home owners (1% and 11% respectively).

Fruit and vegetable intake by selected chronic diseases and health risk factors

- In 2004–05, Indigenous Australians without diabetes were more likely to consume vegetables and fruit on a daily basis than Indigenous Australians with diabetes (Table 2.19.11).
- Indigenous Australians in non-remote areas who reported high levels of physical activity were most likely to consume vegetables on a daily basis, however Indigenous Australians who reported moderate levels of physical activity were most likely to consume fruit on a daily basis.
- Indigenous Australians aged 18 years and over with reported short-term risky/high-risk alcohol consumption were less likely to eat fruit (22% reporting no usual daily fruit intake compared with 13%) and vegetables (8% reporting no usual daily vegetable intake compared with 4%) on a daily basis than those not reporting risky alcohol consumption.
- Indigenous Australians aged 18 years and over who reported being current smokers were more likely to report no usual daily fruit intake and no usual daily vegetable intake than Indigenous persons who were ex-smokers or who had never smoked.

Whether ran out of food in the 12 months before the survey

- In 2004–05, approximately 24% of Indigenous Australians aged 15 years and over reported they ran out of food in the 12 months before the survey compared with 5% of non-Indigenous Australians (Table 2.19.12).
- Approximately 8% of Indigenous people reported they went without food when they couldn't afford to buy more compared with 2% of non-Indigenous people.
- Indigenous Australians aged 15–24, 25–34 and 35–44 years were most likely to report they went without food when they couldn't afford to buy more.
- The proportion of Indigenous Australians who reported they ran out of food in the previous 12 months was much higher in the Northern Territory (45%) than the other states and territories (between 18% and 29%).
- Indigenous Australians aged 15 years and over living in remote areas were more likely to report having run out of food in the last 12 months (36%) than those in non-remote areas (20%).

Dietary behaviour of children aged 4 to 14 years

Fruit and vegetable consumption

- In 2008, approximately 5% of Indigenous children aged 4 to 14 years did not usually eat fruit and 4% did not usually eat vegetables (Table 2.19.13). Approximately 33% had one serve or less of fruit per day and 27% had one serve or less of vegetables per day.

Fruit and vegetable consumption by state/territory

- In 2008, data on the number of serves of fruit and vegetables consumed daily by Indigenous children aged 4 to 14 years was available from New South Wales, Victoria, Queensland and Western Australia. Of these, Victoria had the highest proportion of children with a high daily intake of fruit (65%) and vegetables (7%) and Western Australia had the lowest (58% and 4%, respectively) (Table 2.19.14).

Fruit and vegetable consumption by household characteristics and functional facilities

- The 2008 NATSISS showed that Indigenous children aged 1–14 years in non-remote areas who consumed 1 or less serves of fruit per day were most likely to be in the most disadvantaged (socio-economic index for areas) (1st) quintile (44%), similar to the proportion of children who consumed 2 or more serves per day (45%) (Table 2.19.15).
- Forty-two per cent of Indigenous children who consumed 1 or less serves of vegetables per day were in the most disadvantaged quintile, compared with 34% who consumed 5 serves or more.
- The survey also showed that there was little difference in relation to housing utilisation between children who consumed 1 or less services of fruit per day and those who consumed 2 or more. However, in relation to vegetable consumption, Indigenous children who consumed 5 or more serves per day were less likely to be in a household requiring 1 or more bedrooms than those who consumed 1 or less serves per day (12% compared with 25% respectively) (former figure subject to a large relative standard error).
- Table 2.19.16 presents information on fruit and vegetable consumption in relation to functional facilities, including facilities for washing people and clothes, storing and preparing food, and adequate sewerage. There appears to be little association between the consumption of fruit and vegetables and functioning facilities, with the proportions of fruit and vegetable consumption varying minimally across the four categories of facilities.

Additional information

Research on traditional and non-traditional diets of Aboriginal and Torres Strait Islander people

Poverty and food insecurity have been recognised as important factors in the poor-quality diet of many Indigenous people, especially those living in remote communities. Food prices are generally higher in remote areas for many types of food. The price of basic healthy foods is at least 50% higher in remote locations than in *Major cities* (NHMRC 2003). Foods of better nutritional choice, including fresh fruits and vegetables, are often expensive because of transport and overhead costs, or only minimally available (Shannon 2002). Remote stores, on average, sell half the fruit and one-quarter of the vegetable intake per capita of that of the Australian community overall (Lee et al. 1994). In comparison, takeaway and convenience food items, which are often energy dense and high in fat or sugar, are less affected by issues of cost and availability.

There is evidence to suggest that people living in poverty tend to maximise calories per dollar spent on food. Energy-dense foods rich in fats, refined starches and sugars represent the lowest cost options, whereas healthy diets based on lean meats, whole grains and fresh vegetables and fruits are more costly (Drewnowski & Spencer 2004). A study that analysed the store turnover of food supplies at six remote Indigenous communities in the Northern Territory found a very high consumption of fat and sugar, with fatty meats making the largest contribution to fat intake. In comparison to national consumption data, intake of sweetened carbonated beverages and sugar was much higher in these communities. The proportion of energy derived from refined sugars was approximately four times the recommended intake. The diets of people living in these communities had high levels of animal fat (mainly from poor-quality meat) and very low levels of fruit and vegetables (Lee et al. 1994).

A study that looked at the therapeutic potential of a traditional lifestyle and diet involved a trial of a group of 10 middle-aged Indigenous people with diabetes who were overweight or obese in the West Kimberly region of Western Australia. The group reverted to a traditional hunter-gatherer diet for 7 weeks. After this short time living off their traditional lands, the people involved in the study lost an average of 7 kg and the metabolic abnormalities of diabetes and risk factors for heart disease (blood pressure, blood cholesterol, triglycerides) all improved markedly (O’Dea 1984).

Data quality issues

National Aboriginal and Torres Strait Islander Health Survey

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It has therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities* and *Inner and outer regional* and *Remote and Very remote areas*, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 National Health Survey.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006a).

Dietary behaviour data

The questions on dietary behaviour are complex as respondents needed to understand and apply the inclusions/exclusions, understand the concept of a serve and assess their consumption levels accordingly, and think about their total consumption in what would constitute an average day. Overall, it is considered that the indicators of vegetable and fruit intake in the non-remote component of the 2004–05 NATSIHS are of a lower quality than most other items from the survey, but are considered sufficiently reliable for the purposes of assessing broad intake levels for population groups, and for comparisons between population groups. Using the data for other purposes should be done with care. Data for all those aged 12–14 years, and 68% of those aged 15–17 years, were provided by a proxy, usually a parent. As a result, the data reflect the parent's knowledge of the child's consumption; this is likely to be less accurate for usual consumption of fruit items than for the type of milk and usual consumption of vegetables items collected in non-remote areas (ABS 2006b).

Picture prompt cards were used to help non-remote respondents understand the concept of a serve; one prompt card showed six examples of single serves of different vegetables and another card showed six single serves of fruit. If respondents had difficulty in reporting, interviewers were encouraged to prompt in terms of asking respondents about their usual consumption of vegetables and fruit at breakfast, lunch and dinner and for snacks. Remote respondents were asked whether they usually ate fruit and/or vegetables each day. In addition to products excluded in non-remote areas, fruit or vegetables considered to be bush tucker were also excluded.

In remote areas the questions on vegetable and fruit intake were amended to whether the respondents usually ate fruit and/or vegetables each day. Therefore it is not possible to produce indicators based on usual serves for remote areas from the 2004–05 NATSIHS.

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010).

2.20 Breastfeeding practices

The breastfeeding status of Aboriginal and Torres Strait islander infants, breastfeeding duration, breastfeeding and other sources of food and reasons mothers stopped breastfeeding

Data sources

Data for this measure come from the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS), the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) and the 2010 Infant Feeding Survey.

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

Definitions of breastfeeding terms used in the NATSIHS

Breastfeeding. The child receives some breastmilk but can also receive any food or liquid including non-human milk.

Breastfeeding duration. The total length of time an infant received any breastmilk at all from initiation until weaning is complete.

Ever breastfed. An infant has been put to the breast, even if only once, and/or an infant has received expressed breastmilk but has never been put to the breast.

Exclusively breastfed. An infant has received only breastmilk from his/her mother or a wet nurse or expressed breastmilk and no other liquids or solids with the exception of drops or syrups consisting of vitamins, mineral supplements or medicines.

Predominantly breastfed. An infant's predominant source of nourishment has been breastmilk but the infant has also received water and water-based drinks (sweetened and flavoured water, teas, infusions, etc.); fruit juice; oral rehydration solution; drops and syrup forms of vitamins, minerals and medicines; and/or ritual foods (in limited quantities). All other food-based fluids are excluded, in particular non-human milk.

Fully breastfed. An infant is fully breastfed if he/she receives breastmilk as the main source of nourishment. This includes infants who are either (a) exclusively breastfed or (b) predominantly breastfed—that is, infants with no other liquids or solids (except vitamins, mineral supplements, or medicines) or infants who receive breastmilk and water, water-based drinks, fruit juice, oral rehydration solution, but do not receive breast milk substitutes or solids. The fully breastfed rate is the combined rate of exclusively breastfed and predominantly breastfed (Webb et al. 2001).

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

2010 Australian National Infant Feeding Survey

The 2010 Australian National Infant Feeding Survey (ANIFS) is the first specialised national survey of infant feeding practices in Australia. The survey also collected information on attitudes towards, and enablers for and barriers against breastfeeding. This report provides baseline data on key infant feeding indicators, including: most babies (96%) were initially breastfed, but only 39% were exclusively breastfed for less than 4 months, and 15% for less than 6 months; overall 35% of infants were introduced to solid foods by 4 months of age and 92% by the recommended age of 6 months.

The initial methodology for the ANIFS was developed by the Australian Government Department of Health and Ageing in consultation with Medicare Australia and the Australian Bureau of Statistics (ABS). A pilot study to test the survey method and survey instrument was conducted from August 2010 to September 2010. The main survey was conducted between October 2010 and February 2011.

Data analyses

NATSIHS data

Breastfeeding status

- According to the 2004–05 NATSIHS and NHS surveys, approximately 79% of Indigenous infants aged 0–3 years in non-remote areas had ever been breastfed compared with 88% of non-Indigenous infants (Table 2.20.1).
- At the time of the surveys, approximately 13% of Indigenous infants were currently breastfeeding compared with 16% of non-Indigenous infants (Table 2.20.1).

- A similar proportion of Indigenous and non-Indigenous infants had been breastfed for 12 months or more (13% and 14%, respectively) (Table 2.20.1).
- The maximum duration of breastfeeding among fully breastfed children was 130 weeks for Indigenous children compared with 156 weeks for non-Indigenous children (Table 2.20.1).

Breastfeeding status by state/territory

- In Queensland, a significantly lower proportion of Indigenous infants had ever been breastfed (79%) compared with non-Indigenous infants (89%) (Table 2.20.1). In all other states and territories the difference between the proportion of infants breastfed was not statistically significant between the two population groups.

Breastfeeding status when first taken home from hospital

- In 2004–05, approximately 96% of Aboriginal and Torres Strait Islander infants aged 0–3 years in non-remote areas were breastfed when they were first taken home from hospital (Table 2.20.2). Proportions ranged from 89% in the Australian Capital Territory to 98% in the Northern Territory.

* Represents results with statistically significant differences at the $p<0.05$ level in the Indigenous/non-Indigenous comparisons.

(a) Non-Indigenous results are not provided because the non-Indigenous sample for this area was insufficient for purposes of estimation of these characteristics.

(b) Estimate has a relative standard error of between 25% and 50% and should be used with caution.

(c) Estimate has a relative standard error greater than 50% and are considered too unreliable for general use.

(d) Includes length of time child has been breastfed not known.

(e) Includes breastfeeding status not known.

(f) Excludes children currently breastfed and children who had been fully breastfed for less than 1 week.

(g) Indicates that the maximum length of time breastfed in weeks is greater than this value, but for confidentiality reasons the maximum length of time cannot be released.

Age at which first given solid food

- Over the period 2004–05, Indigenous infants aged 0–3 months in non-remote areas were almost twice as likely to be given solid food as non-Indigenous infants (18% compared with 10%) (Table 2.20.3).
- Over the same period, Indigenous infants aged 3–6 months and 6–9 months in non-remote areas were less likely to be given solid food than non-Indigenous infants of the same age (Table 2.20.3).

Table 2.20.3: Age at which first given solid food regularly, by Indigenous status, persons aged 0–3 years in non-remote areas, 2004–05

	Indigenous	Non-Indigenous	Rate ratio	Rate difference
	%	%	%	%
1–<3 months	18	10	1.8*	8
3–<6 months	34	40	0.9*	–6

Reasons for stopping breastfeeding

- In 2004–05, the main reason mothers of Indigenous infants aged 0–3 years in non-remote areas stopped breastfeeding was that they were no longer producing any or adequate milk (32%).
- Approximately 21% of Indigenous infants were no longer breastfed because mothers felt it was time to stop, and for 6% the mother was pregnant again (Table 2.20.4).
- Approximately 16% of Indigenous infants were no longer breastfed because of other problems with breastfeeding (for example, cracked nipples).

Table 2.20.4: Aboriginal and Torres Strait Islander infants aged 0–3 years, by main reason stopped breastfeeding, non-remote areas, 2004–05

Main reason stopped breastfeeding	Per cent
Not producing any/adequate milk	32
Felt it was time to stop	21
Pregnant	6(a)
Teething	5(a)
Resumed work	4(a)
Child bored	1(b)
Other problems with breastfeeding (e.g. cracked nipples)	16
Not stated	2(b)
Total	**100**
Total no. of infants	**22,941**

(a) Estimate has a relative standard error of between 25% and 50% and should be used with caution.

(b) Estimate has a relative standard error greater than 50% and is considered too unreliable for general use.

Source: ABS and AIHW analysis of 2004–05 NATSIHS.

NATSISS data

Breastfeeding status

- According to the 2008 NATSISS, approximately 77% of Indigenous infants aged 0–3 years had ever been breastfed and 21% of Indigenous infants were currently being breastfed in 2008.
- Approximately 34% of Indigenous infants had breastfeeding stopped at less than 6 months, and 22% had it stopped at 6 months or older (Table 2.20.5).

Breastfeeding status by state/territory

- In New South Wales/Australian Capital Territory a lower proportion of Indigenous infants had ever been breastfed (69%) than in any other jurisdiction (Table 2.20.5).
- In the Northern Territory, a lower proportion of Indigenous infants had breastfeeding stopped at less than 6 months (13%) than in any other jurisdiction (Table 2.20.5).

Breastfeeding status by remoteness

- Breastfeeding status varied by remoteness, with a higher proportion of Indigenous infants aged 0–3 years in remote areas being breastfed than those in non-remote areas. Around 48% of Indigenous infants in remote areas were currently being breastfed, 86% had previously been breastfed and 14% had never been breastfed. This compared with 20%, 75% and 25% respectively of Indigenous infants in non-remote areas.
- At all ages between 0 and 3 years, a higher proportion of Indigenous infants in remote areas had ever been breastfed than those in non-remote areas (Table 2.20.6).

Age at which first given solid food

- In 2008, the majority of Indigenous infants were first given solid food between the ages of 3 and 6 months (43%) and between 6 and 9 months (30%) (Table 2.20.7).
- In 2008, the age at which Aboriginal and Torres Strait Islander children aged 0–3 years were given solid food regularly varied between remoteness areas. In remote areas, the majority (39%) were first given solid food between 6 and 9 months of age. In non-remote areas the majority (50%) were first given solid food between 3 and 6 months of age (Table 2.20.8).

Breastfeeding and other sources of food

- In 2008, around 65% of Indigenous infants aged less than 6 months were never given solid food and around 35% were given solid food (Table 2.20.9).

Table 2.20.9: Whether infant ever given solid food, Indigenous infants aged less than 6 months, 2008

	Number	Proportion (per cent)
Infant given solid food	2,606	34.7
Infant never given solid food	4,897	65.3
Total	**7,503**	**100.0**

Breastfeeding by selected population characteristics and risk factors

Tables 2.20.10 and 2.20.11 present information on Indigenous infants aged 0–3 years by selected health and population characteristics. Proportions in Table 2.20.10 are calculated within a row using the column totals as a denominator; while proportions in Table 2.20.11 are calculated within a column using the total across the rows as a denominator.

- In 2008, 29% of Indigenous infants aged 0–3 years in the lowest (1st) income quintile were never breastfed, compared with 5% in the highest income quintile. Around one-quarter of Indigenous infants in the most disadvantaged (1st) socioeconomic (SEIFA) quintile were never breastfed, compared with only 1% of Indigenous infants in the least disadvantaged (5th) quintile (Table 2.20.10).
- The proportion of Indigenous infants ever breastfed was slightly higher among home owners than renters (82% compared with 76%) (Table 2.20.10).
- Approximately 73% of Indigenous infants who were never breastfed were living in a household with at least one regular smoker compared with 63% of Indigenous infants who were breastfed (Table 2.20.11).

Table 2.20.10: Selected household characteristics by breastfeeding status, Indigenous infants aged 0–3 years, 2008

Australian National Infant Feeding Survey data

- In 2010, the Australian National Infant Feeding survey (ANIFS) found that just over two-thirds (69%) of Indigenous infants aged 1 month received any breastmilk, compared with around three-quarters (75%) of non-Indigenous infants of the same age. By 6 months of age, approximately 45% of Indigenous infants had received any breastmilk compared with 60% of non-Indigenous infants (Table 2.20.12).

Table 2.20.12: Proportion of children receiving any breastmilk, by Indigenous status and age, 2010

	Number		Per cent	
Age (completed months)	**Indigenous**	**Non-Indigenous**	**Indigenous**	**Non-Indigenous**
0[(a)] (less than 1 month)	0	29	0.0.	90.2
1	36	2177	69.2	74.7
2	51	3776	61.4	72.9
3	69	3924	67.3	70.3
4	48	3738	59.2	68.8
5	51	3531	57.3	62.9
6	37	3445	45.4	60.3
7–12	24	2560	21.9	42.4
13–18	18	1727	n.p.	18.5
19–24	22	1569	17.3	7.3

(a) An age of 0 completed months indicates an infant aged from birth to less than 1 month. There were only 33 respondents aged 0 months at the time of survey completion. This was an artefact of the delay between when the sample was drawn and when the survey was completed (for some respondents, this was more than 3 months).

Source: Australian National Infant Feeding Survey 2010.

- Approximately 59% of Aboriginal and Torres Islander infants and 61% of non-Indigenous infants less than one month of age were exclusively breast fed according to the 2010 ANIFS. At less than 3 months, 33% of Indigenous infants were exclusively breastfed compared with 48% of non-Indigenous infants. At less than 6 months, 7% of Indigenous infants were exclusively breastfed compared with 16% of non-Indigenous infants (Table 2.20.13).
- A similar proportion of Indigenous and non-Indigenous infants aged less than 1 month were predominantly breastfed (65%). For infants aged 1 month or more, Indigenous infants were less likely to be predominantly breastfed than non-Indigenous infants (Table 2.20.14).

Table 2.20.13: Duration of exclusively breastfeeding to each month of age by Indigenous status, 2010

		Number		To month	
To month[(a)]	Equivalent duration	Indig.	Non-Indig.	Indig.	Non-Indig.
0	Less than 1 month	344	25149	59.3	61.4
1	Less than 2 months	229	15965	46.2*	56.0*
2	Less than 3 months	177	13313	32.5*	48.1*
3	Less than 4 months	113	9671	18.6*	39.5*
4	Less than 5 months	57	6608	11.0*	27.2*
5	Less than 6 months	19	3552	7.3*	15.5*
6	Less than 7 months	9	1413	—	2.13

* Represents results with statistically significant differences between the Indigenous and non-Indigenous groups at the $p < 0.05$ level.

(a) 'To' indicates an infant's age the months before a fluid other than breastmilk was introduced. This is effectively the month before another fluid was introduced. For example, a child who was introduced to water when they were aged 4 months (in their fifth month of life) was exclusively breastfed to 4 months of age (that is, they had 4 completed months of exclusive breastfeeding). Similarly, a child who was introduced to water at age 1 month (in their second month of life) was exclusively breastfed to 1 month. Or, a child who was introduced to water at 0 months (in their first month of life) was exclusively breastfed to 0 months (or less than 1 month).

Source: Australian National Infant Feeding Survey 2010.

Table 2.20.14: Proportion of children predominately breastfed to each month of age by Indigenous status, 2010

		Number		To month	
To month[(a)]	Equivalent duration	Indig.	Non-Indig.	Indig.	Non-Indig.
0	Less than 1 month	345	25,266	64.9	64.7
1	Less than 2 months	249	17,113	54.3*	60.4*
2	Less than 3 months	200	14,566	40.6*	53.9*
3	Less than 4 months	138	10,881	30.4*	47.4*
4	Less than 5 months	80	7,767	16.6*	34.9*
5	Less than 6 months	28	4,372	10.0*	21.0*
6	Less than 7 months	12	1,864	0.1*	4.0*

* Represents results with statistically significant differences between the Indigenous and non-Indigenous groups at the $p < 0.05$ level.

(a) This indicates an infant's age the month before the event occurred. For example, a child who was introduced to the cow's milk when they were aged 4 months (in their fifth month of life) was predominately breastfed to 4 months of age (that is, they had 4 completed months of predominant breastfeeding).

Source: Australian National Infant Feeding Survey 2010.

- The 2010 ANIFS found that 31% of Indigenous infants aged three months had received soft, semi-solid or solid food in the last 24 hours compared with 9% of non-Indigenous infants. By the time infants reached 5 months, similar proportions of both groups had been given soft, semi-solid or solid food (70%) (Table 2.20.15).

Table 2.20.15: Proportion of children who had received soft/semi-solid/solid food in the last 24 hours, by Indigenous status and current age, 2010

	Number		Per cent

Breastfeeding by selected demographic characteristics

- The 2010 ANIFS found that a higher proportion of Aboriginal and Torres Strait Islander children living in areas in the most advantaged quintile (5th quintile) had been breastfed at some point (99%) compared with children living in the most disadvantaged quintile (1st quintile) (94%) (Table 2.20.17).
- A similar proportion of Indigenous and non-Indigenous children had ever been breastfed in all states and territories except for Victoria where the proportion for Indigenous children was higher.
- Indigenous children living in major cities were slightly more likely to have ever been breastfed than Indigenous children living in regional or remote areas.

Table 2.20.17: Proportion of children ever breastfed, by Indigenous status and area-level characteristics, 2010

	Number		Per cent	
Socio-demographic characteristics	Indig.	Non-Indig.	Indig.	Non-Indig.

Data quality issues

National Aboriginal and Torres Strait Islander Health Survey

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It has therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006a).

Breastfeeding data

The following points should be considered when interpreting data on breastfeeding from the NATSIHS:

- The sample size of infants less than 6 months of age will affect the reliability of estimates.
- Information is 'as reported' by respondents. No analysis has been undertaken regarding the accuracy of these reported data and whether the accuracy of recall by the adult respondent declines as the child gets older.
- In addition, the accuracy of the data may be reduced in cases where an adult other than the child's mother responded regarding the child; this occurred for around 27% of infants aged 0–3 years (21% non-remote, 33% remote).
- Issues relating to the benefits of breastfeeding have been widely promoted in the community and some respondents may have tended to report recommended practices rather than actual practices (ABS 2006b).
- In addition, respondents may not have interpreted the concept 'regularly' in relation to the solids question correctly, where they did not seek clarification from the interviewer. It should also be kept in mind that the inclusion both of infants who are still breastfeeding at the time of the survey and of infants who have ceased breastfeeding may produce estimates that are lower than expected.

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010).

2010 Australian National Infant Feeding Survey

The 2010 Australian National Infant Feeding Survey used two data collection modes: mail-out mail-in and 'online' options. The Australian Institute of Health and Welfare (AIHW) commissioned Educational Assessment Australia (EAA) to undertake formatting and scanning of the survey questionnaire. EAA also formatted and captured the 'online' survey forms. Medicare Australia extracted the sample and managed the mailing out of the survey communications and survey forms. The data collection period for the survey was from October 2010 to February 2011.

The sampling frame for the survey was the Medicare enrolment database. About 52,000 children aged up to 24 months were randomly selected nationwide. Medicare Australia applied an activity test when identifying children for inclusion in the sample. If there was at least one Medicare service or at least one episode recorded in the Australian Childhood

Immunisation Register in the previous 12 months (enrolment was considered an activity), the child was included in the sample (AIHW 2011).

The survey achieved a response rate of 56%, considered to be an exceptional result for a mail survey. Weights were applied to the survey data to adjust for differential probability of selection, differential response rates and also to adjust for non-coverage.

Limitations

As with all self-reported survey data, the major limitation of the survey was that the estimates are based on recall of infant feeding practices. Poor memory, misunderstanding of the question or intentional deception can all contribute to inaccuracies in the data. Further, although the sample size was reasonable for the national level, any estimates for subpopulations are based on a smaller sample size and are less precise.

Since the survey used the Medicare Australia enrolment database, children who were not enrolled at the time of sample selection date were excluded from the survey. Further, Medicare Australia performed an activity test, and only those children who had at least one Medicare service or Australian Childhood Immunisation Register episode in the previous 12 months (including enrolment) were included in the survey.

Only a small proportion of respondents were Indigenous (1.4%; 401 respondents).

Responses are based on mother's/carer's recall of infant feeding practices without reference to written records. As such, the prevalence estimates may overestimate or underestimate actual breastfeeding rates (AIHW 2011).

List of tables

2.21 Health behaviours during pregnancy

The use of tobacco, alcohol, illicit substances and other health issues during pregnancy

Data sources

Data for this measure mainly come from the AIHW National Perinatal Data Collection. Data from the National Aboriginal and Torres Strait Islander Social Survey and The Healthy for Life (HfL) program is also included.

National Perinatal Data Collection

Perinatal data included in this report come from the Australian Institute of Health and Welfare (AIHW) National Perinatal Epidemiology and Statistics Unit National Perinatal Data Collection (NPDC).

Each state and territory has a perinatal collection based on birth notifications completed by midwives and other staff, using information obtained from mothers and from hospital and other records. Perinatal notification forms are completed in Australia for all births of 20 weeks or more gestation, or a birthweight of 400 grams or more.

The Perinatal National Minimum Data Set (NMDS) includes all births in Australia in hospitals, birth centres and the community. State-level data are based on place of mother's usual residence rather than place where birth occurred. Since 2005, all jurisdictions collect information on Indigenous status of the mother in accordance with the Perinatal NMDS. A data item on Indigenous status of the baby was added to the Perinatal National Minimum Data Set from 1 July 2012.

Data on Indigenous status are not reported for Tasmania prior to 2005 as the not stated category for Indigenous status was included with the non-Indigenous category. Data for Tasmania and the Australian Capital Territory are not deemed of sufficient stability to support trends analysis (AIHW: Leeds KL et al. 2007).

Data on mothers for whom Indigenous status was 'not stated' have been excluded from analysis.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of areas of social concern including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including

family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Healthy for Life

The Healthy for Life (HfL) program is an ongoing program funded by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) of the Australian Government Department of Health and Ageing (DoHA). The program aims to improve the capacity and performance of primary health-care services to deliver high-quality maternal, children's and chronic disease care to Aboriginal and Torres Strait Islander people. This is carried out through population health approaches using best-practice and quality improvement principles.

Services participating in the HfL program are required to submit de-identified, aggregate service data for 11 essential indicators. These indicators cover maternal health, child health and chronic disease care on a regular basis (6 and 12 months), as well as information about the characteristics of their service and organisational infrastructure.

The Commonwealth and the AIHW are working with the States and Territories to develop a national Key Performance Indicator (KPI) framework for Indigenous primary health care services. The new National KPIs will replace the *Healthy for Life* program Essential Indicators and cover maternal and child health and chronic disease management. The AIHW is leading the development and refinement of the indicators, data standards and analyses and reporting back to services. The national KPI data collection will be implemented in three stages, with rollout in 2012 and 2013.

Data analyses

Proportions have been age-standardised using the direct age standardisation method to account for differences in the age structure of the Indigenous and non-Indigenous female populations who give birth.

Smoking during pregnancy

Information about smoking during pregnancy for is available for Indigenous and non-Indigenous mothers from the National Perinatal Data Collection. Additional data is available from the 2008 NATSISS, which collected data on selected health issues from Indigenous mothers with children aged 0–3 years.

- In 2009, 52% of Indigenous mothers and 13.2% of non-Indigenous mothers smoked during pregnancy. After adjusting for the different age structures of the two populations, Indigenous mothers smoked during pregnancy at 3.7 times the rate of non-Indigenous mothers (Table 2.21.1).
- The 2008 NATSISS found that 42% of the mothers of Indigenous children aged 0 to 3 years smoked or chewed tobacco during pregnancy. Approximately 18% used more or about the same amount of tobacco during pregnancy and 24% used less (Table 2.21.2).

(continued)

Table 2.21.1 (continued): Tobacco smoking status of mothers during pregnancy, by Indigenous status and state/territory, 2009[(a)(b)]

(a) Excludes births where the mother's Indigenous status was not stated.

(b) Data are by place of usual residence of the mother. Table excludes non-residents, external territories and not stated state/territory of residence.

(c) For women who gave birth in SA, 'Smoked' includes women who quit before the first antenatal visit.

(d) For women who gave birth in SA and the NT, smoking status was recorded at the first antenatal visit.

(e) The proportion of Indigenous women smoked during pregnancy in NT is underestimated and will be increased when smoking status is assigned for the 'not stated' group. Caution should be used when interpreting these rates.

(f) Data are directly age-standardised using the Australian female population who gave birth in 2009.

(g) Rate ratio is the age standardised rate for Indigenous mothers divided by the age standardised rate for non-Indigenous mothers.

Notes

1. Provisional data were provided by Victoria.
2. Because of differences in definitions and methods used for data collection, care must be taken when comparing across jurisdictions. Mother's tobacco smoking status during pregnancy is self-reported.
3. Percentages calculated after excluding records with missing or null values.

Smoking during pregnancy by state/territory

- In 2009, South Australia had the highest proportion of Indigenous and non-Indigenous mothers who smoked during pregnancy (58% and 19% respectively). The largest rate ratio occurred in Western Australia, where Indigenous mothers smoked at 4.3 times the rate for non-Indigenous mothers (Table 2.21.1 and Figure 2.21.1).
- The 2008 NATSISS found the highest proportion of the mothers of Indigenous children aged 0 to 3 years who smoked or chewed tobacco during pregnancy was in South Australia, where 52% of mothers of Indigenous children aged 0 to 3 years smoked or chewed tobacco during pregnancy. The lowest proportion, which was 30%, was in the Australian Capital Territory (Table 2.21.3).

Smoking during pregnancy by remoteness

- In 2009, the proportion of Indigenous mothers who smoked during pregnancy increased with the increasing of remoteness, from 46.4% in major cities to 57.2% in very remote areas. For non-Indigenous mothers, the highest proportion (20%) occurred in outer regional areas. The highest rate ratio was in major cities, where Indigenous mothers were 3.7 times as likely as non-Indigenous mothers to smoke during pregnancy, followed by very remote areas where the rate ratio was 3.5. In inner regional, outer regional and remote areas Indigenous mothers were around three times as likely to smoke during pregnancy as non-Indigenous mothers (Table 2.21.4).
- The 2008 NATSISS found that 47% of mothers of Indigenous children aged 0 to 3 years in remote areas, and 41% in non-remote areas smoked or chewed tobacco during pregnancy (Table 2.21.5).

Smoking during pregnancy by maternal characteristics

- In 2009, a higher proportion of Indigenous mothers smoked during pregnancy than non-Indigenous mothers across all age groups. The rate of smoking by Indigenous and non-Indigenous mothers decreased with increasing age, however this decline was more pronounced for non-Indigenous mothers. Indigenous mothers aged 20–24 years were most likely to smoke during pregnancy (55%), followed by those aged 25–29 years (53%). The lowest percentage was for those aged 40 years and over (46%). For non-Indigenous mothers, the highest proportion occurred for mothers less than 20 years (35%), the lowest proportion (9%) was for mothers in 30–34 and 35–39 age groups (Table 2.21.4).
- In general, the rate of smoking by Indigenous or non-Indigenous mothers decreased with increasing of number of antenatal sessions attended. More than two thirds of Indigenous mothers who only attended one antenatal session smoked during pregnancy; the proportion for mothers having attended at least five sessions was 50.5%. For non-Indigenous mothers, 52% who only attended one antenatal session smoked during pregnancy and 16% who attended at least five sessions smoked during pregnancy (Table 2.21.4).

Smoking during pregnancy by average number of cigarettes smoked per day

- In 2009, of Indigenous mothers who reported smoking during pregnancy in the six jurisdictions combined, over one third (36.5%) smoked an average of more than 10 cigarettes per day (Table 2.21.6).

Table 2.21.6: Indigenous mothers who smoked during pregnancy, by average number of cigarettes per day during second half of pregnancy, by state/territory, 2009[(a)]

(a) Data are by place of usual residence of the mother. Women who gave birth in NSW, Victoria, Queensland, SA, Tasmania, or ACT but reside in another jurisdiction are not reported for this reason. Table excludes non-residents, external territories and not stated state/territory of residence.

(b) For Queensland, Average number of cigarettes smoked per day data were collected from 1 July 2009, therefore, these figures include the July-December period for Queensland only.

(c) For SA, 'Smoked' includes women who quit before the first antenatal visit.

(d) For Tas, smoking data includes all of pregnancy, not just the 2nd half of pregnancy.

Notes

1. Provisional data were provided by Victoria.
2. Because of differences in definitions and methods used for data collection, care must be taken when comparing across jurisdictions. Mother's tobacco smoking status during pregnancy is self-reported.
3. n.p. Data not published to maintain confidentiality of small number.

Source: AIHW (unpublished) National Perinatal Data Collection.

Smoking during pregnancy by baby outcomes

- In 2009, 15% of live-born babies born to Indigenous mothers who smoked during pregnancy were of low birthweight compared with 8% of babies born to Indigenous mothers who did not smoke during pregnancy. For non-Indigenous babies, 10% born to mothers who smoked during pregnancy were of low birthweight compared with 4.5% born to mothers who did not smoke during pregnancy (Table 2.21.7).
- The proportions of babies whose Apgar score was less than 7 at 5 minutes after birth were the same among babies born to Indigenous mothers who smoked during pregnancy and babies born to Indigenous mothers who did not smoke during pregnancy (2.7%) (Table 2.21.7).
- The perinatal death rate for babies born to Indigenous mothers who smoked during pregnancy was higher than the rate for babies born to Indigenous mothers who did not smoke during pregnancy (16 per 1,000 births compared with 14 per 1,000 births).
- During the period 2006–08, 33% of all low birthweight babies born to Indigenous mothers were attributable to smoking during pregnancy, compared with 13% for other Australian mothers. If the smoking rate during pregnancy among Indigenous mothers was the same as it was for other Australian mothers, the proportion of babies with low birthweight among the Indigenous population could be reduced by 24% (Table 2.21.8).
- After adjusting for age differences and all other factors, including pre-term delivery, socioeconomic status, remoteness areas and baby gender, 26% of all low birthweight babies born to Indigenous mothers were attributable to smoking during pregnancy, compared with 9% for other Australian mothers. If the smoking rate during pregnancy among Indigenous mothers was the same as it was for other Australian mothers, after accounting for other factors, the proportion of babies with low birthweight among the Indigenous population could be reduced by 19% (Table 2.21.9).

Alcohol consumption during pregnancy

- According to the NATSISS, in 2008, 3.3% of mothers of Indigenous children aged 0–3 years drank more or the same amount of alcohol during pregnancy, 16% drank less and 80% did not drink at all during their pregnancy (Table 2.21.10).
- The proportion of mothers who did not drink alcohol during pregnancy was greatest in the Northern Territory (85%), and lowest in Victoria and Queensland (77%). The proportion of mothers who drank more or the same amount of alcohol during pregnancy was greatest in Tasmania and the Australian Capital Territory combined (6%) and lowest in South Australia and Queensland (2%) (Table 2.21.10).

Substance use during pregnancy

- According to NATSISS 2008, 5% of the mothers of Indigenous children aged 0–3 years used illicit drugs or substances during pregnancy (Tables 2.21.11, 2.21.12).
- The rate of use of illicit drugs or substances during pregnancy by the mothers of Indigenous children aged 0–3 years was highest in Victoria (9.3%), followed by Western Australia (8.5%). The lowest rate was in New South Wales and Queensland (3.9%) (Table 2.21.11).
- In 2008, the rate use of illicit drugs or substances during pregnancy by the mothers of Indigenous children aged 0–3 years was similar in remote (4.9%) and non-remote areas (5%) (Table 2.21.12).

Health issues of Indigenous mothers during pregnancy

Information about selected health issues of Indigenous mothers during pregnancy is available from the 2008 NATSISS.

- In 2008, 9% of Indigenous mothers in Australia had diabetes or sugar problem during pregnancy; 14% had high blood pressure and 44% took medications or supplements during pregnancy (Table 2.21.13)
- In 2008, the proportion of Indigenous mothers having high blood pressure and took medication or supplements during pregnancy was the highest in Western Australia (20% and 55% respectively) (Table 2.21.13).
- In 2008, about 55% of all Indigenous mothers did not seek advice/information about pregnancy or child birth. The proportion was the highest in the Northern Territory (67%) (Table 2.21.13).
- Indigenous mothers in non-remote areas were less likely to have high blood pressure during pregnancy (14%) in comparison to those in remote areas (16%) (Table 2.21.15). Indigenous mothers in non-remote areas were also less likely to take medications or supplements during pregnancy (41%) in comparison with Indigenous mothers who lived in remote area (54%) (Table 2.21.14).
- Indigenous mothers who sought advice during pregnancy were less likely to smoke during pregnancy than those who did not seek advice (64% compared with 53%), and were more likely to take folate than those who did not (Table 2.21.15).

Healthy for Life data

Data from the period July 2009 to June 2010 on the risk factor status of pregnant women who were regular clients of a Healthy for Life Indigenous primary health-care service, gave birth to an Indigenous baby and attended an antenatal visit are presented below. Risk factor data was collected on smoking status, alcohol consumption and illicit drug use.

- Of mothers who were regular clients of a Healthy for Life Indigenous primary health-care service and attended antenatal care in the first trimester, 55% reported smoking, 30% reported low/high-risk alcohol consumption and 15% reported using illicit drugs in 2009–10 (Table 2.21.16).

Risk factor status by age

- The proportion of women who were regular clients of a Healthy for Life Indigenous primary health-care service, attended antenatal care in the first trimester and who reported smoking during pregnancy was similar across all age groups (Table 2.21.10). For those who attended antenatal care in the third trimester, the rate who reported smoking during pregnancy was lowest in the less than 20 years age group (53%) and highest in the 35 years and over age group (57%) (Table 2.21.17).
- The proportion of women who were regular clients of a Healthy for Life Indigenous primary health-care service, attended antenatal care in the first trimester and who reported low/high-risk alcohol consumption was lowest in the less than 20 years age group (23%) and similar across the other age groups (31%). (Table 2.21.10). For those who attended antenatal care in the third trimester, the proportion who reported low/high-risk alcohol consumption was lowest in the less than 20 years age group (11%) and highest in the 35 years and over age group (29%) (Table 2.21.17).
- The rate of illicit drug use during pregnancy among women who were regular clients of a Healthy for Life Indigenous primary health-care service, and attended antenatal care in the first trimester was highest for women aged 35 years and over (22%). The rates were around 15% for those aged less than 20 years and 20 to 34 years (Table 2.21.16). A similar pattern was observed for women who attended an antenatal visit in the third trimester of pregnancy (Table 2.21.17).

Table 2.21.16: Risk factors status of women[(a)] who gave birth to an Indigenous baby[(b)] who attended an antenatal visit before 13 weeks of pregnancy, by mother's age group, 1 July 2009–30 June 2010

Risk factors	<20 years %	20–34 years %	35 years and over %	Total

Table 2.21.16 (continued): Risk factors status of women[(a)] who gave birth to an Indigenous baby[(b)] who attended an antenatal visit before 13 weeks of pregnancy, by mother's age group, 1 July 2009–30 June 2010

* Represents results with statistically significant differences at the p<0.05 level between <20 years age group and other age groups percentages.

(a) Women who were regular clients of the HfL service.

(b) Women who gave birth to an Indigenous baby in the current reporting period.

(c) Smoker includes daily smokers, weekly smokers and irregular smokers (people who smoke tobacco less than weekly).

(d) Other includes ex-smokers and non-smokers.

(e) Low risk alcohol consumption: a person who over a week has less than 7 standard drinks, or on any one day, has no more than 2 standard drinks (spread over at least two hours). High-risk alcohol consumption: a person who over a week has more than 7 standard drinks, AND on any one day, more than 2 standard drinks.

(f) A person who does not drink at all during pregnancy.

(g) Used illicit drugs include daily, weekly and irregular users (a person who uses less than weekly).

(h) Other includes ex-users and non-users).

Notes

1. This table refers to data provided by a subset of 64 services that provided data by age group and sex.
2. Services used their own definition of regular client.
3. Women whose smoking status, alcohol consumption or illicit drug use status was not recorded were not included the corresponding parts of this table.
4. Numerator is the number of women by smoking status, alcohol consumption or illicit drug use before 13 weeks of pregnancy and Denominator is the total number of women who had an antenatal visit before 13 weeks of pregnancy whose smoking status, alcohol consumption or illicit drug was recorded.

* Represents results with statistically significant differences at the $p<0.05$ level between <20 years age group and other age groups percentages.

(a) Women who were regular clients of the HfL service.

(b) Women who gave birth to an Indigenous baby in the current reporting period.

(c) Smoker includes daily smokers, weekly smokers and irregular smokers (people who smoke tobacco less than weekly).

(d) Other includes ex-smokers and non-smokers.

(e) Low risk alcohol consumption: a person who over a week has less than 7 standard drinks, AND on any one day, has no more than 2 standard drinks (spread over at least two hours). High-risk alcohol consumption: a person who over a week has more than 7 standard drinks, OR on any one day, more than 2 standard drinks.

(f) A person who does not drink at all during pregnancy.

(g) Used illicit drugs include daily, weekly and irregular users (a person who uses less than weekly).

(h) Other includes ex-users and non-users (a person who does not use now and has not used in the last 12 months).

Notes

1. This table refers to data provided by a subset of 63 services that provided data by age group and sex.
2. Services used their own definition of regular client.
3. Women whose smoking status, alcohol consumption or illicit drug use status was not recorded were not included in the corresponding parts of this table.
4. Numerator is the number of women by smoking status, alcohol consumption or illicit drug use in the third trimester of pregnancy and Denominator is the total number of women who had an antenatal visit in the third trimester of pregnancy whose smoking status, alcohol consumption or illicit drug was recorded.

Source: AIHW, Healthy for Life data collection.

Risk factor status by state/territory

- In July 2009 to June 2010, the proportion of women who were regular clients of a Healthy for Life Indigenous primary health-care service, attended antenatal care in the first trimester and reported smoking during pregnancy was similar across all jurisdictions (Table 2.21.18). For women who attended antenatal care in the third trimester, South Australia had the highest proportion who reported smoking during pregnancy (68%) (Table 2.21.19).
- The proportion of women who were regular clients of a Healthy for Life Indigenous primary health-care service, attended an antenatal visit in the first trimester and reported consuming alcohol at low/high levels of risk during pregnancy was not significantly different between jurisdictions (Table 2.21.18). For women who attended antenatal care in the third trimester, Victoria/Tasmania had the highest proportion who reported consuming alcohol at low/high levels of risk during pregnancy (21%), and the Northern Territory had the lowest proportion (12%) (Table 2.21.19).
- In July 2009 to June 2010, South Australia had the highest rate (48%) of reported illicit drug use during pregnancy by women who were regular clients of a Healthy for Life Indigenous primary health-care service and attended an antenatal visit in the first trimester; the lowest reported rate was in the Northern Territory (7%) (Table 2.21.18).

Table 2.21.18: Risk factors status of women[a] who gave birth to an Indigenous baby[b] who attended an antenatal visit before 13 weeks of pregnancy, by state/territory, 1 July 2009–30 June 2010

Risk factor status by remoteness

- From July 2009 to June 2010, the proportion of women who were regular clients of a Healthy for Life Indigenous primary health-care service, attended an antenatal visit in the first trimester and reported smoking during pregnancy was similar across all remoteness areas (Table 2.21.20). A similar pattern was observed for women who attended antenatal care in the third trimester (Table 2.21.21).
- The rate of reported low/high risk alcohol consumption of women who were regular clients of a Healthy for Life Indigenous primary health-care service and attended an antenatal visit in the first trimester was similar across all remoteness areas (Table 2.21.20). For women who attended antenatal care in the third trimester, the rate reported low/high risk alcohol consumption was highest in *Remote* areas (21%) and lowest in *Major cities* (10%) (Table 2.21.21).
- The proportion of women who were regular clients of a Healthy for Life Indigenous primary health-care service, attended an antenatal visit in the first trimester and who reported using illicit drugs during pregnancy was not significantly different across all remoteness areas (Table 2.21.20). For women who attended antenatal care in the third trimester, the rate of reported illicit drug use during pregnancy was highest in *Major cities* (17%) and lowest in *Remote* areas (7%) (Table 2.21.21).

Table 2.21.20: Risk factor status of women[(a)] who gave birth to an Indigenous baby[(b)] who attended an antenatal visit before 13 weeks of pregnancy, by remoteness, 1 July 2009–30 June 2010

Risk factors	Major cities %	Inner regional %	Outer regional %	Remote %	Very remote %	Total
Smoking						
Smoker[(c)]	63.6	50.3	53.1	56.6	63.5	56.0

(continued)

Table 2.21.20 (continued): Risk factor status of women[(a)] who gave birth to an Indigenous baby[(b)] who attended an antenatal visit before 13 weeks of pregnancy, by remoteness, 1 July 2009–30 June 2010

* Represents results with statistically significant differences at the $p<0.05$ level between major cities and other remoteness categories percentages.

(a) Women who were regular clients of the HfL service.

(b) Women who gave birth to an Indigenous baby in the current reporting period.

(c) Smoker includes daily smokers, weekly smokers and irregular smokers (people who smoke tobacco less than weekly).

(d) Other includes ex-smokers and non-smokers.

(e) Low risk alcohol consumption: a person who over a week has less than 7 standard drinks, and on any one day, has no more than 2 standard drinks (spread over at least two hours). High-risk alcohol consumption: a person who over a week has more than 7 standard drinks, or on any one day, more than 2 standard drinks.

(f) A person who does not drink at all during pregnancy.

(g) Used illicit drugs include daily, weekly and irregular users (a person who uses less than weekly).

(h) Other includes ex-users and non-users.

Notes

1. Valid data for this indicator were provided by 65 services (7 in major cities of Australia, 13 in inner regional Australia, 22 in outer regional Australia, 12 in remote Australia and 11 in very remote Australia).
2. Services used their own definition of regular client.
3. Women whose smoking status, alcohol consumption or illicit drug use status was not recorded were not included in the corresponding parts of this table.
4. Numerator is the number of women by smoking status, alcohol consumption or illicit drug use before 13 weeks of pregnancy and Denominator is the total number of women who had an antenatal visit before 13 weeks of pregnancy whose smoking status, alcohol consumption or illicit drug was recorded.

Data quality issues

National Perinatal Data Collection

Births

Birth notification forms are completed for all births of 20 weeks or more gestation, or a birthweight of 400 grams or more. The Perinatal National Minimum Data Set includes all births in Australia in hospitals, birth centres and the community.

Indigenous status question

A standard data item for Indigenous status is specified in the Perinatal National Minimum Data Set. While each jurisdiction has a unique perinatal form for collecting data on which the format of the Indigenous status question and recording categories varies slightly, all systems include the NMDS item on Indigenous status.

Since 2005, all jurisdictions collect information on Indigenous status of the mother in accordance with the NMDS. A data item on Indigenous status of the baby was added to the Perinatal National Minimum Data Set from 1 July 2012.

Under-identification

Data presented by Indigenous status are influenced by the quality and completeness of Indigenous identification of mothers which is likely to differ among jurisdictions and comparisons between states and territories should be interpreted with caution. No formal national assessment has been undertaken to determine completeness of the coverage of Indigenous mothers in the Perinatal NMDS. However, the proportion of Indigenous mothers for the period 2001–2010 has been consistent, at 3.6–3.9% of women who gave birth. Approximately 0.3% of mothers who gave birth in 2009 had missing Indigenous status information. Mothers for whom Indigenous status was not stated have been excluded from analyses. No adjustments have been made for under-identification or missing information.

In 2007, the NPESU, in collaboration with the AIHW's Aboriginal and Torres Strait Islander Health and Welfare Unit, released a report on Indigenous mothers and their babies in each state and territory. This report was based on a survey which was sent to the midwifery managers across Australia to determine how many hospitals in each jurisdiction obtain Indigenous status information of mothers giving birth from admission records and how many collect this information independently. The assessment also involved analysis of the variability in the number and proportion of mothers recorded as Indigenous in the perinatal data collection over time and across jurisdictions for the period 1991–2004. The outcomes of this assessment showed that Indigenous status data from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory are suitable for trends analysis. Perinatal data from the Australian Capital Territory and Tasmania, although improving, were deemed to be of insufficient quality. This project included an assessment of Indigenous status data quality (Leeds et al. 2007).

All jurisdictions are working towards improving the quality of Indigenous status data in their perinatal data collections.

State/territory data

Analysis by state/territory is based on the usual residence of the mother unless otherwise stated. Data excludes Australian non-residents of external territories and where the state/territory of residence was not stated.

Data on Indigenous status are not reported for Tasmania before 2005 because the 'not stated' category for Indigenous status was included with the non-Indigenous category.

Smoking during pregnancy data

There is currently no data element in the Perinatal National Minimum Data Set for smoking during pregnancy, however some information is obtained as part of the NPDC. A program for national data development was completed in 2009 to add nationally agreed data items on smoking during pregnancy to the Perinatal NMDS from July 2010.

For 2009, data on smoking during pregnancy was available from all states and territories.

Definitions used for smoking during pregnancy differ among the jurisdictions. All states and territories currently collect at least one smoking question as part of their routine perinatal data collections. Data for the Northern Territory and South Australia relate to smoking status at the first antenatal visit. For South Australia, smoked includes women who quit before the first antenatal visit. This may result in higher rates of smoking being reported for these jurisdictions because often the first antenatal visit will precede pregnancy-related harm minimisation interventions designed to stop smoking during pregnancy. Given the different timing of data collection on smoking during pregnancy in the different jurisdictions, comparisons between states and territories should be interpreted with caution.

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors

Care has been taken to ensure that the results of this survey are as accurate as possible. All interviews were conducted by trained ABS officers. However, some factor may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010a).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User's guide (ABS 2010a).

Healthy for Life data

For the July 2009 to June 2010 reporting period, 79 services submitted data as part of the Healthy for Life (HfL) Program.

Services started submitting their data through an electronic interface (OSCAR) for the February 2008 reporting period. This has improved the quality of data submitted.

Not all of the services were able to provide data for all of the essential indicators and service profile questions included in the HfL data collection. The number of services that were able to provide data varies across the qualitative and quantitative indicators.

There has been an upward trend in the proportion of services that reported on each of the indicators over time, particularly compared with the first reporting period ending June 2007. All of the services reporting provided data for all of the EIs in the period ending December 2009. This proportion decreased slightly in the current reporting period ending June 2010. This may be because services need to report against fewer Essential Indicators (EI) and do not need to provide most qualitative data in periods ending in December, unlike in annual reporting periods ending in June. The current period had higher proportions of services that reported against most EIs than the previous annual collection period ending June 2009.

In general, the data quality improved noticeably between the period ending June 2008 and the period ending June 2009. The overall level of data quality remained similar in the current period, though there was a different pattern of data quality issues.

The current period ending June 2010 had a different distribution of data quality issues than the previous period. No services had inconsistencies between related indicators, however the number of services with missing data and data out of the expected range increased. The latter might be due to more stringent data checking procedures employed by the AIHW during the current period.

List of tables

List of figures

2.22 Overweight and obesity

The prevalence of overweight and obesity among Aboriginal and Torres Strait Islander adults and children

Data sources

Data on the prevalence of overweight and obesity among Aboriginal and Torres Strait Islander adults come from the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS).

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

Data for this measure are based on information collected on self-reported height and weight. These measures were used to calculate body mass index (BMI) and categorise respondents into categories of underweight, acceptable weight, overweight and obese. Note that, for approximately 16% of Indigenous Australians and 8% of non-Indigenous Australians, self-reported height and weight were not known or not stated.

Based on the *National health data dictionary*, BMI cut-offs for adults are as follows:

- overweight is a BMI of at least 25 kg/m^2 and less than 30 kg/m^2
- obese is a BMI of at least 30 kg/m^2.

For children, overweight and obesity are defined using the same BMI cut-offs as for adults after adjusting for age and sex.

Data analyses

No data are currently available on the prevalence of overweight and obesity among Aboriginal and Torres Strait Islander children. The Australian Aboriginal and Torres Strait Islander Health Survey, to be conducted as part of the Australian Health Survey 2012–13, will collect information on the physical measures of height and weight that will be used to calculate the body mass of children.

Prevalence of overweight and obesity

- In 2004–05, of those with a known body mass index, approximately 4% of Indigenous Australians aged 18 years and over were underweight, 36% were of acceptable weight, 29% were overweight and 31% were obese (Table 2.22.1).
- After adjusting for differences in age structure, in 2004–05, Indigenous adults were slightly more likely than non-Indigenous adults to be underweight (4% compared with 3%); less likely to be of acceptable weight (32% compared with 44%); less likely to be overweight (31% compared with 36%) and much more likely to be obese (34% compared with 18%) (Table 2.22.1).

Prevalence of overweight and obesity by age and sex

- Both Indigenous and non-Indigenous adults were most likely to be overweight or obese at ages 45–54 years and 55 years and over. In these age groups, between 69% and 74% of Indigenous people, and between 61% and 59% of non-Indigenous people, were overweight or obese.
- A higher proportion of Indigenous males were overweight (34%) compared with Indigenous females (24%). However, Indigenous females were more likely to be obese than Indigenous males (34% compared with 28%), and also more likely to be underweight than Indigenous males (6% compared with 3%) (Table 2.22.1).

Prevalence by selected population and health characteristics

- In 2004–05, Indigenous Australians aged 18 years and over were more likely to be overweight/obese if they had a self-assessed health status of fair/poor rather than excellent/very good (68% compared with 55%); reported three or more long-term health conditions rather than no long term-health conditions (65% compared with 56%); reported circulatory problems (72% compared with 57% with no circulatory problems); had diabetes (83% compared with 57%); or did not have cancer (60% compared with 42%) (Table 2.22.2).
- A higher proportion of Indigenous adults in the highest (5th) household income quintile were overweight/obese compared with the lowest (1st) (61% compared with 59%). Those in the lowest income quintile were more likely to be underweight (7%) than those in the highest (3%).
- There was little difference between the proportions of overweight/obese Indigenous adults in the lowest (1st) socioeconomic (SEIFA) quintile (61%) and those in the highest (5th) (60%).
- Indigenous adults whose highest year of school completed was Year 12 were more likely to be overweight/obese than those whose highest year of school completed was Year 9 or below (64% compared with 57%).
- In 2004–05, Indigenous adults who were employed were slightly more likely to be overweight/obese (61%) than those who were unemployed (59%) or not in the labour force (60%).
- Indigenous adults who reported being current smokers were more likely to be underweight (6%) and less likely to be overweight/obese (54%) than those who reported never smoking (3% and 65%, respectively) or being an ex-smoker (2% and 69% respectively).
- Indigenous adults who reported no daily vegetable intake were more likely to be underweight (8%) and less likely to be overweight/obese (49%) than those who reported eating vegetables daily (4% and 61%, respectively).

(a) SEIFA refers to Socio-Economic Indexes for Areas developed by the ABS. The SEIFA Indexes allow ranking of regions/areas which provide a method of determining the level of socioeconomic wellbeing in that region.

(b) Non-remote areas only.

Note: Excludes those with an unknown BMI (39,583 or 15%).

Source: AIHW analysis of 2004–05 NATSIHS.

Time series analyses

- There has been no significant change in the prevalence of overweight and obesity among Indigenous Australians between 2001 and 2004–05 (59% and 60%, respectively, among those with a known BMI).
- In non-remote areas of Australia, approximately 51% of Indigenous Australians were overweight or obese in 1995, which was lower than the proportions reported in 2001 (56%) and 2004–05 (60%) (Table 2.22.3).
- For non-Indigenous Australians aged 18 years and over, there was a slight increase in the proportion who were overweight or obese between 2001 and 2004–05 (48% and 53%, respectively, among those with a known BMI) (ABS 2006b).

Table 2.22.3: Proportion of Indigenous Australians aged 18 years and over who are overweight/obese, by remoteness, 1995, 2001 and 2004–05

Additional information

Studies of the links between obesity, poverty and nutrition in the Indigenous population

A number of studies have investigated the links between obesity and factors such as poverty and diet in the Indigenous population.

Available data show that when Aboriginal and Torres Strait Islander people lived a traditional lifestyle, they generally had a low body mass index compared with what is considered normal for European Australians, and their weight did not tend to increase with age (O'Dea 2008; MIMS Consumer Health Group 2003). Poverty and food insecurity have been recognised as important factors in the poor-quality diet of many Indigenous people, especially those living in remote communities. Food prices are generally higher in remote areas for many types of food. The price of basic healthy foods is at least 50% higher in remote locations than in *Major cities* (NHMRC 2003). Foods of better nutritional choice, including fresh fruits and vegetables, are often expensive because of transport and overhead costs, or only minimally available (Shannon 2002). Remote stores on average sell half the fruit and one-quarter of the vegetable intake per capita of that of the overall Australian community overall (Lee et al. 1994). In comparison, takeaway and convenience food items, which are often energy-dense and high in fat or sugar, are less affected by issues of cost and availability.

There is evidence to suggest that people living in poverty tend to maximise calories per dollar spent on food. Energy-dense foods rich in fats, refined starches and sugars represent the lowest cost options, whereas healthy diets based on lean meats, whole grains and fresh vegetables and fruits are more costly (Drewnowski & Spencer 2004). A study that analysed the store turnover of food supplies at six remote Indigenous communities in the Northern Territory found a very high consumption of energy, fat and sugar, with fatty meats making the largest contribution to fat intake. In comparison to national consumption data, intake of sweetened carbonated beverages and sugar was much higher in these communities. The proportion of energy derived from refined sugars was approximately four times the recommended intake. The diets of people living in these communities had high levels of animal fat (mainly from poor-quality meat) and very low levels of fruit and vegetables (Lee et al. 1994).

Several studies have looked at the effect of traditional and non-traditional diets on BMI and weight gain in the Indigenous population. A study which looked at the therapeutic potential of a traditional lifestyle and diet involved a trial of a group of 10 middle-aged Indigenous people with diabetes who were overweight or obese in the West Kimberly region of Western Australia. The group reverted to a traditional hunter-gatherer diet for 7 weeks. After this short time living off their traditional lands, the people involved in the study lost an average of 7 kg. In addition, the metabolic abnormalities of diabetes and risk factors for heart disease (blood pressure, blood cholesterol, triglycerides) all improved markedly (O'Dea 1984). The Indigenous people involved in the trial also became more confident and assertive while they were in the bush and became proud of their local knowledge and skills. These were deemed important factors in improving the BMI and physical health of Indigenous people (O'Dea 1984). Successful prevention of obesity in some Indigenous outstations has been associated with greater physical activity, consumption of bush foods and ownership of, and access to, traditional homelands (Rowley et al. 2000, cited in O'Dea et al. 2007).

Data quality issues

National Aboriginal and Torres Strait Islander Health Survey

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It has therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006a).

Overweight and obesity data

The quality of BMI as a measure of overweight and obesity has a number of issues: the reliability of self-reported height and weight; under-reporting; mixed methods of collection of weight and height; and interpretation of BMI cut-offs in children.

Self-reported height and weight has been found to over-estimate height and under-estimate weight, thus under-estimating the resultant BMI. An analysis of the 1995 National Health Survey and 1995 National Nutrition Survey (ABS 1998), in which both self-reported and measured height and weight data were collected, found that 27% of males and 28% of females would have been classified to a different, predominately heavier, BMI category. This analysis did not explore data from the Aboriginal and Torres Strait Islander respondents; however, there was little difference between different ethnic and socioeconomic groups. The report concludes:

Based on the findings from this study, there may be grounds for questioning the reliability, and hence the use and interpretation, of BMI results based on self-reported height and weight.

In the 2004–05 NATSIHS and 2004–05 National Health Survey, height and weight information could not be obtained for approximately 16% of Indigenous Australians and 8% of non-Indigenous Australians. With a large non-response rate there may be issues with bias. In the 1994 NATSIHS an assessment of potential bias due to non-measurement concluded that there would have been only small differences if the whole population was measured; however, this assessment was based on an imputation method that assumed that people with similar characteristics had similar weight and height (Cunningham & Mackerras 1998).

Height and weight were self-reported in the 2004–05 National Health Survey except in remote areas where respondents to the Indigenous survey were offered the opportunity to be weighed or measured if they were unsure of their weight or height (ABS 2006a). Given the known problems with self-reporting of height and weight, care needs to be exercised in interpretation of results given the mixed methods used, especially when the analysis is split by remoteness.

List of tables

Tier 3 Health System Performance

3.01 Antenatal care

Number, rate and percentage of Indigenous women who used antenatal care provided by skilled birth attendants for reasons related to pregnancy at least once during pregnancy among all women who gave birth, whether resulting in a live or stillbirth, if the birthweight was at least 400 grams or the gestational age was 20 weeks or more

Data sources

Data for this measure come from the National Perinatal Data Collection, the 2008 National Aboriginal and Torres Strait Islander Social Survey and the Healthy for Life data collection.

National Perinatal Data Collection

Perinatal data included in this report come from the Australian Institute of Health and Welfare (AIHW) National Perinatal Epidemiology and Statistics Unit National Perinatal Data Collection (NPDC).

Each state and territory has a perinatal collection based on birth notifications completed by midwives and other staff, using information obtained from mothers and from hospital and other records. Perinatal notification forms are completed in Australia for all births of 20 weeks or more gestation, or a birthweight of 400 grams or more.

The Perinatal National Minimum Data Set (NMDS) includes all births in Australia in hospitals, birth centres and the community. State-level data are based on place of mother's usual residence rather than place where birth occurred. Since 2005, all jurisdictions collect information on Indigenous status of the mother in accordance with the Perinatal NMDS. A data item on Indigenous status of the baby was added to the Perinatal National Minimum Data Set from 1 July 2012.

Data on Indigenous status are not reported for Tasmania prior to 2005 as the not stated category for Indigenous status was included with the non-Indigenous category. Data for Tasmania and the ACT are not deemed of sufficient stability to support trends analysis (AIHW: Leeds et al. 2007).

Data on mothers for whom Indigenous status was 'not stated' have been excluded from analysis.

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Healthy for Life

The Healthy for Life (HfL) program is an ongoing program funded by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) of the Australian Government Department of Health and Ageing (DoHA). The program aims to improve the capacity and performance of primary health-care services to deliver high-quality maternal, children's and chronic disease care to Aboriginal and Torres Strait Islander people. This is carried out through population health approaches using best-practice and quality improvement principles.

Services participating in the HfL program are required to submit de-identified, aggregate service data for 11 essential indicators. These indicators cover maternal health, child health and chronic disease care on a regular basis (6 and 12 months), as well as information about the characteristics of their service and organisational infrastructure.

The Commonwealth and the AIHW are working with the States and Territories to develop a national Key Performance Indicator (KPI) framework for Indigenous primary health care services. The new National KPIs will replace the *Healthy for Life* program Essential Indicators and cover maternal and child health and chronic disease management. The AIHW is leading the development and refinement of the indicators, data standards and analyses and reporting back to services. The national KPI data collection will be implemented in three stages, with rollout in 2012 and 2013.

Analyses

National Perinatal Data Collection

Data on the use of antenatal care services are available for New South Wales, Queensland, South Australia, the Australian Capital Territory and the Northern Territory. Data for the year 2009 are presented for all of these states and territories except for the Australian Capital Territory, which reported that the quality of antenatal care data in the Territory for the year 2009 was poor and was not reliable enough to publish.

Use of antenatal care services by state/territory

- In 2009, in New South Wales, Queensland, South Australia and the Northern Territory combined, 97% of Indigenous mothers and 99% of non-Indigenous mothers attended at least one antenatal care session (Table 3.01.1).
- The proportions of Indigenous mothers who attended at least one antenatal care session was 89% in South Australia, 95% in the Northern Territory and 98% in New South Wales and Queensland.
- In New South Wales and Queensland, the rate at which Indigenous mothers attended at least one antenatal care session during pregnancy was similar to non-Indigenous mothers, whilst in South Australia and the Northern Territory, the rate of attendance at antenatal care was lower for Indigenous than non-Indigenous mothers (Table 3.01.1).

Use of antenatal care services by remoteness

- In 2009, there was little difference in the proportion of Indigenous mothers who attended at least one antenatal care session by remoteness (97% in non-remote areas and 96% in remote areas) (Table 3.01.2).

Use of antenatal care services by age

- Across all age groups in 2009, for New South Wales, Queensland, South Australia and the Northern Territory combined, the percentage of Indigenous mothers who attended at least one antenatal care session during pregnancy was similar to non-Indigenous mothers (Table 3.01.3).
- The largest difference between the proportion of Indigenous and non-Indigenous mothers attending at least one antenatal session can be observed for mothers aged 40 years and over. In this age group 96% of Indigenous mothers attended one session compared with 99% of non-Indigenous mothers.

(a) Indigenous and non-Indigenous data exclude births where the mother's Indigenous status is not stated.

(b) Data not available from the Victoria, Western Australia and Tasmania. Data are available in the ACT but are not of sufficient quality to publish.

(c) Total women who gave birth in the period, whether resulting in a live or still birth, if the birthweight is at least 400 grams or the gestational age is 20 weeks or more.

(d) Data are directly age-standardised using the Australian female population who gave birth in 2009.

(e) Data for Qld, SA and NT only. Women who gave birth in Queensland, SA or the NT but reside in another jurisdiction are not reported due to small numbers. Data not collected in NSW. These data are not generalisable to Australia.

Note: Number of antenatal visits and Gestation at first antenatal visit are not part of the Perinatal NMDS. The current question is not consistent across jurisdictions, therefore, caution should be used when interpreting these numbers.

Source: AIHW (unpublished) National Perinatal Data Collection.

Use of antenatal care services by smoking status

- Smoking status made little difference to the likelihood of attendance at antenatal sessions for Indigenous mothers.
- In 2009, in New South Wales, Queensland, South Australia and the Northern Territory combined, 97% of Indigenous mothers who smoked attended at least one antenatal session during pregnancy, compared with 98% of Indigenous mothers who did not smoke. A similar pattern can be observed for non-Indigenous mothers (Table 3.01.4).

Table 3.01.4: Use of antenatal services by mothers, by smoking status and Indigenous status, NSW, Qld, SA and NT, 2009[a][b]

Use of antenatal care services and birth outcomes

Tables 3.01.5, 3.01.6 and 3.01.7 present information on mothers who attended antenatal sessions and specific birth outcomes. Table 3.01.5 presents information on birthweight, Table 3.01.6 presents information on pre-term babies (less than 37 weeks gestation) and Table 3.01.7 presents information on perinatal deaths.

In 2009, in New South Wales, Queensland, South Australia and the Northern Territory combined, among Indigenous mothers who gave birth to a live baby and attended at least one antenatal session:

- 10% gave birth to a baby of low birthweight. This compared with 5% of non-Indigenous mothers (Table 3.01.5).
- The proportion who give birth to pre-term babies was 1.6 times that for non-Indigenous mothers (Table 3.01.6).
- 1.6% had babies that died in the perinatal period (the perinatal period commences at 20 completed weeks, or 140 days, of gestation and ends 28 completed days after birth) , compared with 0.8% of non-Indigenous mothers (Table 3.01.7).

Time series analyses

Data on the antenatal care used by Indigenous mothers are available for 1998–2009 for New South Wales, South Australia and Queensland, and 2000–2009 for the Northern Territory.

- Over the period 1998–2009, in New South Wales, Queensland and South Australia combined, there was a significant increase in the rate at which Indigenous mothers attended at least one antenatal care session during pregnancy. The fitted trend implies an average annual increase in the rate of around 3.4 per 1,000 women who gave birth, which is equivalent to a 4.0% increase in the rate over the period. Over the same period, there was also a significant increase in the rate at which non-Indigenous mothers attended at least one antenatal care session during pregnancy (1.7% increase) (Table 3.01.8; Figure 3.01.1).
- In New South Wales, over the period 1998–2009, there was a significant increase in the rate at which Indigenous mothers attended at least one antenatal care session during pregnancy (average annual increase of 3.7 per 1,000; 4.4% increase over the period). Over the same period, there was a slight decrease in the rate at which non-Indigenous mothers attended at least one antenatal care session during pregnancy (0.1% decrease) (Table 3.01.8).
- In Queensland, over the period 1998–2009, there was a significant increase in the rate at which Indigenous mothers attended at least one antenatal care session during pregnancy (average annual increase of 0.7 per 1,000; 0.8% increase). For non-Indigenous mothers there was a significant decrease (0.3%) in the rate of antenatal care attendance during pregnancy.
- In South Australia, over the period 1998–2009, there was a significant increase in the rate at which Indigenous mothers attended at least one antenatal care session during pregnancy (average annual increase of 21 per 1,000; 33% increase). Over the same period, there was also a significant increase in the rate at which non-Indigenous mothers attended at least one antenatal care session during pregnancy (16% increase).
- In the Northern Territory, over the period 2000–2009, there were no significant changes in the rates at which Indigenous mothers or non-Indigenous mothers attended at least one antenatal care session during pregnancy. The data show that the Northern Territory had the highest rate of mothers attending antenatal visits (reaching 1,000 per 1,000 for non-Indigenous women and 999 per 1,000 for Indigenous women in 2005 and 2006) and also the least difference between Indigenous and non-Indigenous women. Northern Territory data are not presented for 1998, 1999 and 2002 because of a technical error.

Table 3.01.8: Mothers who attended at least one antenatal care session (age-standardised rats per 1,000 women), by Indigenous status, NSW, Qld, SA, ACT and NT, 1998–2009[(a)(b)]

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 1998–2009.

(a) Indigenous and non-Indigenous data exclude births where the mother’s Indigenous status is not stated.

(b) Jurisdiction-level data are based on place where birth occurred, not place of usual residence. Data not available from Victoria, Western Australia and Tasmania. Data are available in the ACT but are not of sufficient quality to publish.

(c) Average annual change in rates and rate ratios determined using linear regression analysis.

(d) Per cent change between 1998 and 2007 based on the average annual change over the period.

(e) In 2007 NSW collected data for a new variable "was antenatal care received", which provides a more accurate picture of the use of antenatal sessions. Prior to 2007 data for the number of women attending antenatal sessions in NSW was restricted to those whose 'duration of pregnancy at first antenatal session was recorded". In order to maintain consistency in the time series data using the pre-2007 definition is used.

(f) SA data excludes women where number of antenatal care sessions attended is unknown.

(g) In the NT in 1998, 1999 and 2002, a system error occurred where a large number of women had birthing records created with no antenatal data attached. NT average annual change in rates and rate ratios and per cent change based on the period 2003 to 2007.

(h) NT average annual change in rates and rate ratios and per cent change based on the period 2003 to 2007.

Note: Number of antenatal visits and Gestation at first antenatal visit are not part of the Perinatal NMDS. The current question is not consistent across jurisdictions, therefore, caution should be used when interpreting these numbers.

Figure 3.01.1: Proportion of mothers who attended at least one antenatal care session, by Indigenous status, NSW, Qld and SA combined, 1998–2009

Pregnancy check-up and type of health professional consulted

Information on check-ups while pregnant along with the type of health professional consulted was collected in 2008 NATSISS.

- A total of 96% of women with children aged 0–3 years reported that they had check-ups during pregnancy: 92% reported having regular check-ups, while about 4.7% reported having check-ups but not regularly (Table 3.01.9).
- More than half of Indigenous mothers (61%) reported consulting a doctor or GP for pregnancy check-ups and almost half (48%) consulted a midwife or nurse. An obstetrician was consulted by 17%, while 8.8% consulted an Aboriginal or Torres Strait Islander Health Worker.

Table 3.01.9: Use of antenatal service by Indigenous mothers, by type of service, children aged 0–3 years, 2008

	Number	Per cent
Whether child's mother had regular pregnancy check-ups		
Had regular check-ups while pregnant	47,014	91.5
Had check-ups while pregnant but not regular	2,390	4.7

Distance to hospital or clinic where child was born

- Approximately 47% of the Indigenous children aged 0–3 years in 2008 were born in a hospital or clinic less than 10 kilometres from where the child's birth mother lived when the child was born (Table 3.01.10).
- About 19% of Indigenous children aged 0–3 years in 2008 were born in a hospital or clinic 10–24 kilometres away.
- Around one in ten (11%) children were born in a hospital or clinic 250 kilometres or more away.
- Only a small proportion (1%) of Indigenous children were not born in a hospital or clinic.

Table 3.01.10: Distance to hospital or clinic where child was born, Indigenous children aged 0–3 years, 2008

	Number	Per cent
Less than 10 kilometres	24,331	46.9
10–24 kilometres	9,816	18.9
25–49 kilometres	4,526	8.7
50–99 kilometres	3,351	6.5
100–249 kilometres	3,641	7.0
250 kilometres or more	5,640	10.9
Child not born in a hospital or clinic	567	1.1

Use of antenatal services by health issues

Data from the 2008 NATSISS were cross-tabulated to examine whether women with a health issue had used an antenatal service during pregnancy.

- Of women who reported that they had diabetes or sugar problems while pregnant, 96% had used an antenatal service during pregnancy, and of those with high blood pressure 95% had used an antenatal service (Table 3.01.11). These proportions were similar to those who did not have diabetes or sugar problems (96%) or who did not have high blood pressure (97%).
- Almost all Indigenous women who took folate during pregnancy also sought antenatal services (99%), and about 93% who did not take folate had check-ups while pregnant.

Table 3.01.11: Use of antenatal service by Indigenous mothers, by selected health issues, children aged 0–3 years, 2008

Use of antenatal care services funded by the Healthy for Life program

Information on the antenatal care of mothers who attended services funded through the Healthy for Life (HfL) Program is available from the AIHW HfL data collection.

- In the reporting period ending June 2010, 66 Indigenous primary health-care services which were part of the HfL program provided valid data on antenatal care. Of the 2,057 women who gave birth to an Indigenous baby who were regular clients of these services, 49% attended their first antenatal visit in the first trimester of pregnancy (before 13 weeks) and 68% undertook their first visit before 20 weeks of pregnancy (Table 3.01.12).
- Of the women who gave birth to an Indigenous baby in the reporting period, a higher proportion of mothers from regional or remote areas attended their first antenatal visit in their first trimester of pregnancy than mothers in urban areas (ranging from 48% to 56% in regional and remote areas, compared with 38% in major cities) (Table 3.01.12).
- The proportion of mothers who attended their first antenatal visit before 20 weeks of pregnancy was 57% in major cities, 74% in inner regional areas, 65% in outer regional areas and 71% in both remote and very remote areas.
- Women aged under 20 years were less likely than those aged 20 and over to undertake their first antenatal visit before 13 weeks of pregnancy (41% of those aged under 20, and 51% and 48% of those aged 20–34 and 35 years and over respectively) (Table 3.01.13).
- In relation to states and territories, the proportion of women who attended their first antenatal visit before 13 weeks of pregnancy ranged from 43% in South Australia to 55% in New South Wales and the Australian Capital Territory combined (Table 3.01.14).

Table 3.01.12: Number and proportion[(a)] of women[(b)] who gave birth to an Indigenous baby[(c)], by timing of the first antenatal visit, by remoteness, 1 July 2009–30 June 2010

Timing of first antenatal visit	**Major cities**	**Inner regional**	**Outer regional**	**Remote**	**Very remote**	**Total**
			Per cent			
Before 13 weeks of pregnancy	38.1*	55.9*	47.7*	49.6*	49.3*	48.5
At 13 weeks or after, but before 20 weeks of pregnancy	19.3*	18.5*	16.9*	21.2*	21.6*	19.0
Before 20 weeks of pregnancy	*57.4**	*74.4**	*64.6**	*70.8**	*70.9**	*67.5*
At 20 weeks of pregnancy or after	23.3*	16.9*	20.2*	22.8*	19.4*	20.5
Did not attend/Not recorded antenatal visit	19.3*	8.6*	15.2*	6.4*	9.7	12.0
Total	**223**	**313**	**791**	**452**	**278**	**2,057**

* Represents results with statistically significant differences at the $p < 0.05$ level between major cities and other remoteness categories percentages.

(a) Numerator is the number of women who attended an antenatal visit and denominator is the total number of women who gave birth to an Indigenous baby.

(b) Women who were regular clients of the HfL service.

(c) Women who gave birth to an Indigenous baby in the current reporting period.

Notes

1. Valid data for this indicator were provided by 66 services (6 in major cities of Australia, 13 in inner regional Australia, 23 in outer regional Australia, 13 in remote Australia and 11 in very remote Australia).
2. Services used their own definition of regular client.

Data quality issues

National Perinatal Data Collection

Births

Birth notification forms are completed for all births of 20 weeks or more gestation, or a birthweight of 400 grams or more. The Perinatal National Minimum Data Set includes all births in Australia in hospitals, birth centres and the community.

Indigenous status question

A standard data item for Indigenous status is specified in the Perinatal National Minimum Data Set. While each jurisdiction has a unique perinatal form for collecting data on which the format of the Indigenous status question and recording categories varies slightly, all systems include the NMDS item on Indigenous status.

Since 2005, all jurisdictions collect information on Indigenous status of the mother in accordance with the NMDS. A data item on Indigenous status of the baby was added to the Perinatal National Minimum Data Set from 1 July 2012.

Under-identification

Data presented by Indigenous status are influenced by the quality and completeness of Indigenous identification of mothers which is likely to differ among jurisdictions and comparisons between states and territories should be interpreted with caution. No formal national assessment has been undertaken to determine completeness of the coverage of Indigenous mothers in the Perinatal NMDS. However, the proportion of Indigenous mothers for the period 2001–2010 has been consistent, at 3.6–3.9% of women who gave birth. Approximately 0.3% of mothers who gave birth in 2009 had missing Indigenous status information. Mothers for whom Indigenous status was not stated have been excluded from analyses. No adjustments have been made for under-identification or missing information.

In 2007, the NPESU, in collaboration with the AIHW’s Aboriginal and Torres Strait Islander Health and Welfare Unit, released a report on Indigenous mothers and their babies in each state and territory. This report was based on a survey which was sent to the midwifery managers across Australia to determine how many hospitals in each jurisdiction obtain Indigenous status information of mothers giving birth from admission records and how many collect this information independently. The assessment also involved analysis of the variability in the number and proportion of mothers recorded as Indigenous in the perinatal data collection over time and across jurisdictions for the period 1991–2004. The outcomes of this assessment showed that Indigenous status data from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory are suitable for trends analysis. Perinatal data from the ACT and Tasmania, although improving, were deemed to be of insufficient quality. This project included an assessment of Indigenous status data quality (AIHW: Leeds et al. 2007).

All jurisdictions are working towards improving the quality of Indigenous status data in their perinatal data collections.

State/territory data

Analysis by state/territory is based on the usual residence of the mother unless otherwise stated. Data excludes Australian non-residents of external territories and where the state/territory of residence was not stated.

Data on Indigenous status are not reported for Tasmania before 2005 because the ‘not stated’ category for Indigenous status was included with the non-Indigenous category.

Antenatal care data

Currently, data on antenatal care is not available from all jurisdictions. Data reported for 2009 on number of women who gave birth who attended at least one antenatal visit in the first trimester are for New South Wales, South Australia and the Northern Territory for the whole year and in Queensland for the second half of the year only. Data reported for 2009 on number of antenatal visits are for Queensland, South Australia and the Northern Territory only. Residents of these jurisdictions who gave birth in a different jurisdiction would not have data on antenatal care.

Proportions of records missing antenatal care information on whether the first visit was in the first trimester are very different for women who resided in New South Wales (1.1%), Queensland (3.5%), and the Northern Territory (1.8%) compared with South Australia (10.9%). Improvements in data validation in the Northern Territory, including validation against date of first of ultrasound examinations attended, has led to improved data quality and a decrease in the proportion of records missing antenatal care information, since 2007. The timing of the first visits for women missing data may be distributed differently to those whose data have been reported. There are also differences in how the jurisdictions define antenatal visits.

Healthy for Life data

For the July 2009 to June 2010 reporting period, 79 services submitted data as part of the Healthy for Life (HfL) Program.

Services started submitting their data through an electronic interface (OSCAR) for the February 2008 reporting period. This has improved the quality of data submitted.

Not all of the services were able to provide data for all of the essential indicators (EIs) and service profile questions included in the HfL data collection. The number of services that were able to provide data varies across the qualitative and quantitative indicators.

There has been an upward trend in the proportion of services that reported on each of the indicators over time, particularly compared with the first reporting period ending June 2007. All of the services reporting provided data for all of the EIs in the period ending December 2009. This proportion decreased slightly in the current reporting period ending June 2010. This may be because services need to report against fewer EIs and do not need to provide most qualitative data in periods ending in December, unlike in annual reporting periods ending in June. The current period had higher proportions of services that reported against most EIs than the previous annual collection period ending June 2009.

In general, the data quality improved noticeably between the period ending June 2008 and the period ending June 2009. The overall level of data quality remained similar in the current period, though there was a different pattern of data quality issues.

The current period ending June 2010 had a different distribution of data quality issues than the previous period. No services had inconsistencies between related indicators, however the number of services with missing data and data out of the expected range increased. The latter might be due to more stringent data checking procedures employed by the AIHW during the current period.

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6,900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. Trained ABS officers conducted all interviews. However, some factors may affect the reliability of the data.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010–11. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *National Aboriginal and Torres Strait Islander Social Survey: User's guide 2008* (ABS 2010).

3.02 Immunisation

Vaccination coverage rates among Indigenous Australian children and adults

Data sources

Data for this measure come mainly from the Australian Childhood Immunisation Register (ACIR), and the National Aboriginal and Torres Strait Islander Health Survey (NATSIHS).

The Australian Childhood Immunisation Register (ACIR)

The ACIR is a national register that records details of vaccinations given to children under seven years of age who live in Australia. Immunisation coverage is produced at the national, state/territory and local level on a quarterly basis using the data recorded on the ACIR.

Coverage estimates for Aboriginal and Torres Strait Islander children include only those who identify as such and are registered on the ACIR. Children identified as Indigenous on the ACIR may not be representative of all Aboriginal and Torres Strait Islander children, and thus coverage estimates should be interpreted with caution.

Vaccination coverage is a measure of the proportion of people in a target population who have received the recommended course of vaccinations at a particular age.

In this report, children for whom Indigenous status was not stated are included with 'non-Indigenous' under the 'other' category.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS).

Analyses

Childhood immunisation

In May 2005, the National Immunisation Program (NIP) schedule replaced the Australian Vaccination Schedule, and funds all recommended vaccines. From November 2005, the NIP schedule for children included vaccines for hepatitis B, diphtheria-tetanus-pertussis (DTP), haemophilus influenza type B (HIB), measles, mumps, rubella (MMR) and polio (NCIRS 2007, 2008). In more recent years vaccines have been included for pneumococcal disease, meningococcal C, Varicella (chickenpox), rotavirus, human papillomavirus (HPV) and influenza.

Vaccination coverage rates for children aged 1 year, 2 years and 5 years as at 31 December 2011 are presented below.

- Aboriginal and Torres Strait Islander children had slightly lower coverage for all vaccines at 1 year of age than other Australian children (85% of Indigenous children fully immunised compared with 92% of other Australian children), and had similar coverage at 2 years of age (92.3% vs 92.6%) and 5 years of age (87% and 90% respectively) (Table 3.02.1).
- For states and territories, vaccination coverage for all vaccines for Indigenous children aged 1 year ranged from 77% in South Australia to 93% in Tasmania. Indigenous children had lower coverage for all vaccines in all jurisdictions except Tasmania (Table 3.02.2).
- Vaccination coverage for all vaccines for Indigenous children aged 2 years ranged from 86% in South Australia and the Australian Capital Territory to 96% in the Northern Territory. Vaccination coverage rates were lower for Indigenous children compared with other Australian children aged 2 years in Western Australia, South Australia and the Australian Capital Territory, slightly higher in the Northern Territory, and similar in all other states and territories (Table 3.02.3).
- Vaccination coverage rates for all vaccines for Indigenous children aged 5 years ranged from 80% in South Australia to 91% in the Northern Territory. Coverage rates for Indigenous children aged 5 years were higher than non-Indigenous children in the Northern Territory, but lower or similar in all other states and territories (Table 3.02.4).

Time series analyses

Longer term trend data are limited to five jurisdictions—New South Wales, Victoria, Western Australia, South Australia and the Northern Territory. Data from the Australian Capital Territory, Queensland and Tasmania have not been included because information on Indigenous status from these jurisdictions has not been routinely reported or transferred to the ACIR in previous years.

- Between 2001 and 2011, in New South Wales, Victoria, Western Australia, South Australia and the Northern Territory combined, there was little change in the proportion of Indigenous children and other children who were fully vaccinated at one year of age (82% to 85% for Indigenous children and 90% to 92% for other children), however, the increase for other children was statistically significant (Table 3.02.5; Figure 3.02.1).
- Between 2001 and 2011, there was no significant change in the proportion of Indigenous children who were fully immunised at 2 years of age (89% to 92%), while there was a significant increase of 5% over the period for non-Indigenous children (from 87% to 93%) (Table 3.02.5; Figure 3.02.2).
- Between 2008 and 2011, there was a statistically significant increase in the proportion of Indigenous children who were fully vaccinated at 5 years of age (from 76% to 87%) as well as in the proportion of non-Indigenous children (from 79% to 90%) (Table 3.02.5; Figure 3.02.3).
- Between 2002 and 2007, there was a statistically significant increase in the proportion of children who were fully vaccinated at 6 years of age (from 83% to 85%), as well as in the proportion of non-Indigenous children (from 82% to 89%) (Table 3.02.5; Figure 3.02.4).

Adolescent immunisation

From September 2003, the National Immunisation Program Schedule recommended catch-up hepatitis B vaccination for adolescents of one cohort within the age range of 10–13 years who had no prior history of disease or vaccination (NCIRS 2008).

The 2004–05 NATSIHS and NHS provide data on coverage for the hepatitis B vaccine for adolescents aged 10–17 years living in non-remote areas, which is not covered by the ACIR.

- In 2004–05, the proportions of Indigenous and non-Indigenous adolescents who had completed hepatitis B vaccination were comparable (51% and 50%, respectively).
- There were some variations across the states and territories, although the differences between Indigenous and non-Indigenous were not statistically significant (NCIRS 2008).

Adult immunisation

Aboriginal and Torres Strait Islander adults aged 50 years or over, and those aged 15 to 49 years with medical conditions putting them at high risk of disease or complications, are recommended for vaccination against influenza and pneumococcal disease. These two vaccines have been provided through the National Indigenous Pneumococcal and Influenza Immunisation (NIPII) Program since 1999. For non-Indigenous adult Australians, the recommended age to receive these two vaccines is 65 years or over, and has been funded through the Influenza Vaccine Program for Older Australians since 1999 and the Pneumococcal Vaccination Program for Older Australians since January 2005 (NCIRS 2008).

The 2004–05 NATSIHS and NHS provide data on coverage for the influenza and pneumococcal vaccines in adults, as well as the presence of high-risk medical conditions that are indicators for vaccination in younger adults.

Risk factors

Influenza

The risk factors for which the influenza vaccine is recommended include at least one of many chronic medical conditions including severe asthma, diabetes mellitus, and chronic cardiovascular, respiratory and kidney conditions (NCIRS 2008).

- In 2004–05, approximately 17% of Indigenous Australians aged 18–49 years reported at least one of the chronic medical conditions that were considered risk factors of influenza for which vaccination was recommended. The proportion with at least one risk factor rose to 29% when current asthma was included (Table 3.02.6).
- Influenza vaccination coverage varied across jurisdictions. The highest influenza vaccination coverage was reported in the Northern Territory, where 55% of those who reported at least one risk factor, and 48% of the total Indigenous population aged 18–49 years, reported having the influenza vaccination in the last 12 months (Table 3.02.6).
- Of the 23% of the Indigenous population aged 18–49 who reported having the influenza vaccination in the last 12 months, 8% had at least one risk factor and 15% had no risk factors (NCIRS 2008).

Pneumococcal

The risk factors for which the pneumococcal vaccine is recommended include at least one of many chronic medical conditions (but not including asthma), heavy alcohol use and tobacco smoking (NCIRS 2008).

- In 2004–05, the proportion of Indigenous Australians aged 18–49 years who reported at least one of the chronic medical conditions and heavy alcohol use was 32%, which then rose to 66% when tobacco smoking was added (Table 3.02.7).
- Pneumococcal vaccination coverage varied across jurisdictions. The highest pneumococcal vaccination coverage was reported in the Northern Territory, where 25% of those who reported at least one risk factor, and 26% of the total Indigenous population aged 18–49 years, reported having the influenza vaccination in the last 5 years (Table 3.02.7).
- Of the 12% of the Indigenous population aged 18–49 who reported having the pneumococcal vaccination in the last 5 years, 9% had at least one risk factor and 3% had no risk factors (NCIRS 2008).

Immunisation for adults aged 50 years and over

Data on immunisation of Indigenous persons aged 50 years and over come from the 2004–05 NATSIHS and are presented below.

Immunisation status by sex and Indigenous status

- In 2004–05, 60% of Indigenous persons aged 50 years and over had been vaccinated against influenza in the last 12 months and 15% had been vaccinated against influenza but not in the last 12 months. These proportions were higher than those reported in 2001 (51% and 10%, respectively) (Table 3.02.8).
- A slightly higher proportion of Indigenous females aged 50 years and over had been vaccinated against influenza in the last 12 months (61%) than Indigenous males (58%).
- A substantially higher proportion of Indigenous persons aged 50 years and over in remote areas had been vaccinated against influenza in the last 12 months (80%) than in non-remote areas (52%).
- In 2004–05, approximately 34% of Indigenous persons aged 50 years and over had been vaccinated against pneumonia in the last 5 years, which was substantially higher than the proportion recorded in 2001 (25%).
- A higher proportion of Indigenous females aged 50 years and over had been vaccinated against pneumonia in the last 5 years (37%) than Indigenous males (31%).
- Indigenous persons aged 50 years and over in remote areas were more than twice as likely to have been vaccinated against pneumonia in the last 5 years as Indigenous persons in non-remote areas (56% compared with 26%).
- In 2004–05, a higher proportion of Indigenous persons aged 65 years and over had been vaccinated against influenza and pneumonia (84% and 48%, respectively) than non-Indigenous persons of the same age (73% and 43%, respectively) (Table 3.02.9).
- However, comparisons of vaccination coverage among Indigenous and non-Indigenous Australians for pneumococcal and influenza need to take into account differences in the age at which vaccinations are funded and provided free of charge for the different population groups. In 2004–05, a lower proportion of Indigenous persons aged 50 years and over had been vaccinated against influenza in the last 12 months and pneumonia in the last 5 years (60% and 34%, respectively) than non-Indigenous persons aged 65 years and over (73% and 43%, respectively) (Figure 3.02.5).

Figure 3.02.5: Immunisation status, Indigenous persons aged 50 years and over and non-Indigenous persons aged 65 years and over, 2004–05

Immunisation status by access to health care and selected population characteristics

- In 2004–05, over half of all Indigenous Australians (aged 50 years and over in non-remote areas) who had never been vaccinated against influenza or pneumonia had accessed health care in the last 2 weeks (53% and 58%, respectively). Approximately 25% of Indigenous Australians who had never been vaccinated against influenza had been admitted to hospital in the last 12 months and 26% had consulted with other health professionals in the last 2 weeks. Approximately 26% of Indigenous people aged 50 years and over who had never been vaccinated against pneumonia had been admitted to hospital in the last 12 months, 34% had consulted with a doctor in the last 2 weeks and 22% had consulted with other health professionals (Table 3.02.10).
- Indigenous people who have been vaccinated against influenza or pneumonia were more likely than those who have not been vaccinated to have accessed health care in the last two weeks (Table 3.02.10).
- A higher proportion of Indigenous Australians aged 50 years and over who spoke a language other than English at home had had an influenza vaccination in the last 12 months and a pneumonia vaccination in the last 5 years than Indigenous Australians who spoke English as their main language at home (Table 3.02.11).
- Indigenous Australians aged 50 years and over who were in the lowest household income quintile were more likely than those in the highest income quintiles to have had influenza and pneumonia vaccinations, as were those in the 1st quintile of the index of disparity (most disadvantaged) compared with the 5th quintile (least disadvantaged). Indigenous Australians who were renters were more likely than home owners to have received the vaccinations.

How influenza vaccination was obtained

- In 2004–05, for approximately 43% of Indigenous Australians aged 50 years and over in non-remote areas, influenza vaccinations were provided free of charge (Table 3.02.12). In 2001, approximately 30% of Indigenous Australians aged 50 years and over in non-remote areas received influenza vaccinations free of charge, compared with 67% of non-Indigenous Australians.

Self-reported data

Childhood immunisation

The 2004–05 NATSIHS provided information on the immunisation status of Indigenous children aged 0–6 years in non-remote areas of Australia. Data from this survey, and the 2001 NHS, which collected information on the immunisation status of Indigenous and non-Indigenous children, are presented below.

- Of Indigenous children aged 0–6 years in non-remote areas who had immunisation records available, approximately 94% were fully immunised in 2001 and 93% were fully immunised in 2004–05. Around 4% of Indigenous children aged 0–6 years were partially immunised in 2001 and 7% were partially immunised in 2004–05 (Table 3.02.13).
- In 2004–05, 78% of Indigenous children aged 0–6 years in non-remote areas were fully immunised against diphtheria/tetanus, 74% against whooping cough, 82% against hepatitis B, 78% against polio, 72% against HIB and 84% against measles, mumps and rubella.
- The proportion of Indigenous children fully immunised in 2001 was similar to 2004–05 for all diseases, with the exception of polio, for which coverage was higher in 2001 (88%), and HIB, for which coverage was lower in 2001 (67%).

- In 2001, in non-remote areas, the proportion of Indigenous and non-Indigenous children who were fully immunised was similar (88% and 92% respectively), but Indigenous children were around twice as likely to be partially immunised (6% compared with 3%).
- The most common factors influencing the decision to immunise children aged 0–6 years for Indigenous people in non-remote areas in 2004–05 were 'for the child's health' (88%), 'it was believed to be the right thing to do' (51%) and 'the child must be immunised to go to child care/school' (29%) (Table 3.02.14). Similar proportions of Indigenous and non-Indigenous people in non-remote areas reported these factors as influencing their decision to immunise children in 2001.

Data quality issues

The Australian Childhood Immunisation Register (ACIR)

Registrations

The ACIR was established in 1996. The data used are from an administrative data collection, for which there is an incentive payment for notification, and further incentives for parents to have their child's vaccination status up to date. The Register is linked to the Medicare enrolment register and approximately 99% of children are registered with Medicare by 12 months of age.

Data have been reported using the ACIR definition of fully-immunised children; that is, children who have received all age appropriate immunisations for diphtheria, tetanus, pertussis, hepatitis B, polio, haemophilus influenza type B, measles, mumps and rubella. The varicella (chickenpox) vaccine was added to the NIPS for children born from 1 May 2004; the pneumococcal vaccine was added to the NIPS for children born from 1 January 2005; and the rotavirus vaccine was added to the NIPS for children born from 1 May 2007.

Although there are now more vaccines (including meningococcal C, human papillomavirus (HPV), and influenza (for at-risk groups)) on the National Immunisation Program Schedule for children than reported here, these are not in scope for those children aged five years at the time of reporting.

A minimum 3-month lag period is allowed for late notification of immunisations to the Register.

Indigenous status question

Indigenous identification is collected via a 'yes/no' flag on immunisation encounter forms, and through Medicare offices when any changes are made to personal details. Medicare uses the standard definition of Indigenous status; however, these details are converted to a 'yes' or 'no' when reports on vaccination coverage are produced from the ACIR. The immunisation encounter form method of Indigenous identification is voluntary and relies on the immunisation provider seeking the information.

Vaccination coverage

General limitations of data available from the ACIR must be considered when used to estimate vaccination coverage. ACIR coverage estimates could overestimate or under-estimates coverage, depending on whether those children not identified as Indigenous Australian have higher or lower than average vaccination coverage.

Vaccination coverage for children is measured by the ACIR. The Register records vaccinations for each child when they are reported by doctors and other service providers. Coverage figures for the total child population from the ACIR under-estimate true coverage by about 2–3% because of unreported vaccinations. Coverage for Aboriginal and Torres Strait Islander children is probably less accurate than that, because not all Indigenous children are recorded as Indigenous on the ACIR. Some Indigenous children are recorded as "unknown" Indigenous status (DoHA 2006).

Vaccination coverage data from the ACIR and the NATSIHS are not directly comparable because of the differences in the cohort used, population coverage, data collection method, method of calculating 'fully immunised' and vaccines included.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The 2004–05 NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys

with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in Major cities, Inner and outer regional areas and Remote and very remote areas, but Very remote areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In Remote and very remote communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

List of tables

List of figures

3.03 Health promotion

Interventions provided by clinicians and health promotion initiatives funded by governments and provided by a range of health professionals in the wider community for the Aboriginal and Torres Strait Islander population

Data sources

Data for this indicator come from the AIHW Health expenditure database, the Bettering the Evaluation and Care of Health (BEACH) survey data, Healthy for life data, the Community Housing and Infrastructure Needs Survey data (CHINS) and OATSIH Services Reporting data collection (OSR).

Health expenditure data

Data on health expenditure comes from the AIHW health expenditure database. The AIHW reports biennially on expenditure on health for Aboriginal and Torres Strait Islander people. The latest report in the series, *Expenditure on health for Aboriginal and Torres Strait Islander people 2008–09,* was released in 2011.

In some areas of expenditure, surveys have been used to estimate service use by Indigenous people, which, in turn, have been used in the estimates of expenditure. In other areas of expenditure, administrative data such as hospital admissions and Medicare Voluntary indigenous identifier data has been used in expenditure estimates. Other (non-health) agency contributions to health expenditure, such as health expenditures incurred within education departments and prisons, are not included

Estimates of the level of Indigenous under-identification were used to adjust some reported expenditure reported in this indicator. In some states and territories, a single state wide average under-identification adjustment factor was applied. In others, differential under-identification factors were used, depending on the region in which the particular service(s) were located. In some jurisdictions, no Indigenous under-identification adjustment was considered necessary.

Bettering the Evaluation and Care of Health (BEACH) survey

Information about encounters in general practice is available from the BEACH survey, which was conducted by the AIHW Australian General Practice Statistics and Classification Centre, in the Family Medicine Research Centre (FMRC) at the University of Sydney until March 2012, when the AIHW ceased its involvement in the BEACH program. The FMRC continues to run BEACH the results are now published by the University of Sydney. The most recent annual reports can be found at http://ses.library.usyd.edu.au/handle/2123/7771.

Information is collected from every changing random sample of approximately 1,000 general practitioners (GPs) from across Australia each year. A sample of 100 consecutive GP–patient encounters is collected by each GP.

The number of Indigenous patients identified in the BEACH survey is likely to be underestimated because some GPs might not ask the question on Indigenous status, or the patient may choose not to identify themselves (AIHW 2002).

Data are presented for the 5-year period 2006–07 to 2010–11, during which there were around 6,000 GP encounters with Aboriginal and Torres Strait Islander patients recorded in the survey, representing 1.2% of total GP encounters.

Healthy for Life

The Healthy for Life (HfL) program is an ongoing program funded by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) of the Australian Government Department of Health and Ageing (DoHA). The program aims to improve the capacity and performance of primary health-care services to deliver high-quality maternal, children's and chronic disease care to Aboriginal and Torres Strait Islander people. This is carried out through population health approaches using best-practice and quality improvement principles.

Services participating in the HfL program are required to submit de-identified, aggregate service data for 11 essential indicators. These indicators cover maternal health, child health and chronic disease care on a regular basis (6 and 12 months), as well as information about the characteristics of their service and organisational infrastructure.

The Commonwealth and the AIHW are working with the States and Territories to develop a national Key Performance Indicator (KPI) framework for Indigenous primary health care services. The new National KPIs will replace the Healthy for Life program Essential Indicators and cover maternal and child health and chronic disease management. The AIHW is leading the development and refinement of the indicators, data standards and analyses and reporting back to services. The national KPI data collection will be implemented in three stages, with rollout in 2012 and 2013.

Community Housing and Infrastructure Needs Survey (CHINS)

The Community Housing and Infrastructure Needs Survey (CHINS) collects data from all Aboriginal and Torres Strait Islander housing organisations and discrete Aboriginal and Torres Strait Islander communities in Australia. The latest CHINS was enumerated from 1 March to 30 June 2006. The data were collected through personal interviews with key community and Indigenous Housing Organisation (IHO) representatives knowledgeable about housing and infrastructure issues. The survey collected information on all Aboriginal and Torres Strait Islander communities throughout Australia. The Australian Bureau of Statistics (ABS) conducted the 2006 CHINS on behalf of, and with full funding from, the Department of Families, Community Services and Indigenous Affairs (FaCSIA). Information collected includes:

- details of current housing stock, dwelling management practices and selected income and expenditure arrangements of Indigenous organisations that provide housing to Aboriginal and Torres Strait Islander people
- details of housing and related infrastructure, such as water, electricity, sewerage, drainage, rubbish collection and disposal, as well as other facilities such as transport, communication, education, sport and health services, available in discrete Aboriginal and Torres Strait Islander communities.

The 2006 information was collected on 496 Indigenous housing organisations which managed a total of 21,854 permanent dwellings. Information was also collected on 1,187 discrete Indigenous communities with a combined population of 92,960. Most of these communities were in *Very remote* regions of Australia, with 73% (865) having a population fewer than 50 people.

OATSIH Services Reporting data collection (OSR)

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Analyses

Government expenditure

Government expenditure on selected public health activities for Indigenous and non-Indigenous Australians in 2008–09 is presented in Table 3.03.1 and Figure 3.03.1 below.

- In 2008–09, state/territory government expenditure on core public health activities was $116.9 million for Indigenous Australians and $1,554.9 million for non-Indigenous Australians.
- State/territory government expenditure per person on core public health activities was higher for Indigenous persons than non-Indigenous persons ($214 compared with $73).
- The Indigenous share of state/territory government expenditure was 18% for cervical cancer screening, 11% for prevention of hazardous and harmful drug use, 11% for public health research and 10% for communicable disease control.
- Of the core public health activities, organised immunisation received the most state/territory government expenditure per person for Indigenous Australians ($62).

- State/territory government expenditure per person was higher for Indigenous Australians than for non-Indigenous Australians for all core public health activities, except breast cancer screening.
- The ratio of Indigenous to non-Indigenous per person expenditure was highest for cervical cancer screening (8.3) and lowest for breast cancer screening (0.5).

Table 3.03.1: State and territory government health expenditure, for Indigenous Australian and non-Indigenous people on core public health services, 2008–09

	Expenditure ($ million)			Expenditure per person ($)

GP prevention and early intervention programs

The Annual Survey of Divisions collects data on prevention and early intervention programs run by Divisions of General Practice. Divisions reported a total number of 7 035 practices in Australia at 30 June 2011 (Carne et al. 2012). The number and proportion of Divisions targeting specific population groups in their prevention and early intervention programs or activities for 2010–11 is presented in Table 3.03.2.

- In 2010–11, 99% of general practice divisions ran programs for immunisation and Type II diabetes; 96% for mental health; over 80% ran programs for health promotion, physical activity, healthy weight/obesity and nutrition; 69% for cervical screening, 65% for alcohol and other drugs; 55% for smoking; 26% for breast cancer screening; 17% for skin cancer screening; 14% for bowel cancer screening and 20% for injury prevention.
- In 2010–11, 90% of Divisions had at least one prevention/early intervention program aimed at Indigenous Australians. Seventy-three per cent of divisions focused on Indigenous Australians in their immunisation programs, 67% in their Type II diabetes programs, 63% in their health promotion programs, 58% in mental health programs, 56% in programs for smoking, 52% in healthy weight and obesity programs, 51% in their alcohol and other drug programs, 48% in their physical activity programs, 46% in their nutrition programs, 41% for breast cancer screening, 40% for cervical screening, 25% for bowel cancer screening and 11% for skin cancer screening.

Table 3.03.2: Number and proportion of Divisions of General Practice with selected prevention/early intervention programs and number and proportion of Divisions aiming at Indigenous Australians in their prevention and early intervention programs, 2010–11

	Divisions with program/activity		Indigenous Australians	
Selected prevention programs	**Number**	**Per cent[(a)]**	**Number**	**Per cent[(a)]**
Immunisation	110	99	80	73

Bowel cancer screening	16	14	4	25
Other activities	13	12	7	54
At least one program/activity	111	100	100	90

(a) Proportions are calculated using the number of Divisions with the specified program or activity as the denominator.

Source: Carne et al. 2012.

- Between 2004–05 and 2010–11 there has been a continual increase in the number of Divisions with Type II diabetes and health promotion (Table 3.03.3).
- Over the same period, there has been an increase in the proportion of Divisions that focused on Indigenous Australians in their immunisation, Type II diabetes, health promotion, physical activity, alcohol and other drugs, cervical screening and breast cancer screening programs (Table 3.03.3).
- Between 2004–05 and 2010–11 there was an increase in the proportion of Divisions that focused on Indigenous Australians in their alcohol and other drugs, and smoking programs (Table 3.03.3).
- In 2010–11, almost all divisions provided immunisation or diabetes programs (99% respectively), as well as mental health programs (96%). Divisions reported activity increases for immunisation, diabetes, health promotion, nutrition, breast cancer screening, and injury prevention, with a 5% increase in alcohol and other drugs activities or programs on the previous year.

Clinical treatments provided by general practitioners

Information on clinical treatments provided by general practitioners such as advice, education and counselling for smoking, alcohol, nutrition, weight, exercise and lifestyle are available from the BEACH survey. Data for the 5-year BEACH reporting periods April 2006–March 2007 to April 2010–March 2011 are provided below.

- Over the period April 2006–March 2011, of the 3,648 clinical treatments provided to Indigenous patients surveyed in the BEACH, 11.2% were for general advice/education, 5.3% were for counselling/advice related to treatment, 6.0% were for advice/education related to nutrition and weight, 3.2% were for counselling/advice related to smoking, 1.8% were for counselling/advice related to alcohol and 1.6% were for counselling/advice related to exercise (Table 3.03.4; Figure 3.03.2).
- The selected clinical treatments related to health promotion outlined above were provided at a rate of 191 per 1,000 encounters for Indigenous patients. Of these, general advice/education (68 per 1,000 encounters) and counselling/advice related to nutrition and weight were the most common treatments provided (37 per 1,000 encounters) (Table 3.03.4).
- After adjusting for differences in the age structure of the two populations, 'Counselling/advice related to smoking' was provided to Indigenous patients at 2.6 times the rate for non-Indigenous patients. 'Counselling/advice related to alcohol' was provided in 2% of all the clinical treatment among Indigenous patients which was over 2.5 times the rate for non-Indigenous patients (Table 3.03.4).
- The rate of total clinical treatments provided to Indigenous and to other patients fluctuated over the 13 year period April 1998–March 1999 to April 2010–March 2011 (Table 3.03.5). The fluctuation may be due to an influence of the introduction of practice nurses and Aboriginal Health Workers which were introduced in 2005–06 (Britt et al. 2012).
- At encounters with Indigenous patients, general advice and education; counselling and advice for smoking; counselling and advice for alcohol; counselling and advice for lifestyle; and family planning were provided more often in the BEACH survey year April 2010–March 2011 than in April 1998–March 1999. Although these differences were not statistically significant (Table 3.03.6).
- Over the period April 2006–March 2007 to April 2010–March 2011, clinical treatments related to health promotion were more commonly provided by GPs to Indigenous patients than other patients in the management of cardio-vascular problems (Table 3.03.7). For other problems, the rate of clinical treatments provided to Indigenous and other patients were similar.

Indigenous communities

Health promotion programs

Health promotion programs are defined in the CHINS as 'a series of planned group activities conducted by a health professional within the community'. They are designed to change knowledge, attitudes, beliefs, behaviours or susceptibility to disease through a combination of educational and environmental measures, screening or immunisation (ABS 2007).

For the 2006 CHINS, data on health promotion programs were only collected from communities that completed the long community questionnaire. The health promotion questions in the CHINS do not collect information on the extent or quality of these activities —only that they have occurred. Therefore, these data are limited in providing information about the health promotion activities occurring in these discrete Indigenous communities.

- In 2006, most discrete Indigenous communities reported that one or more selected health promotion programs (67%) had been conducted, with women's health programs reported by 58%, well babies programs by 54%, immunisation programs by 54% and men's health programs by 52% of communities (Table 3.03.8; Figure 3.03.3).
- The proportion of discrete Indigenous communities reporting at least one health promotion program varied across jurisdictions. Queensland had the highest proportion (89%) and New South Wales the lowest proportion (50%) (Table 3.03.9).
- The proportion of discrete Indigenous communities reported conducting at least one health promotion program decreased from 82% in 2001 to 75% in 2006 (Table 3.03.10; Figure 3.03.4).
- In 2001 and 2006 the three most commonly run health promotion programs for discrete Indigenous communities were women's health, well babies and immunisation (Table 3.03.10; Figure 3.03.4).

Table 3.03.8: Discrete Indigenous communities[(a)] located 10 kilometres or more from a hospital: selected health promotion programs conducted in community, 2006

	Health promotion program conducted		Health promotion program not conducted	
	Communities (number)	Communities (per cent)	Communities (number)	Communities (per cent)

Figure 3.03.4: Proportion of communities with each type of health promotion program conducted, 2001 and 2006

Frequency of health promotion programs

- The frequency with which health promotion programs were conducted in discrete Indigenous communities varied by program. The majority of programs were most likely to be conducted weekly or monthly, except for trachoma control and eye health, both of which were most likely to be conducted less than 3-monthly (Table 3.03.11).

OATSIH Services Reporting (OSR) data

Programs/activities provided

All Indigenous primary health-care services undertake a number of extended care roles to support their communities. The data in this section refer to the proportion of Indigenous primary health-care services included in the OSR data collection that undertake these roles through the provision of programs and activities, but not the extent to which they are undertaken or the amount of resources used to carry out these activities.

In 2010–11, there were 236 Indigenous primary health-care services included in the OSR of which 235 (99.6%) responded to the OSR questionnaire (AIHW 2012).

Preventative health care and screening

- In 2010–11, 92% of Indigenous primary health care services offered health promotion/education programs, 78% routinely organised influenza immunisation and offered women's health programs and 77% offered child immunisations (Figure 3.03.5).

Health related and community services

- In 2010–11, around 90% of Indigenous primary health care services provided transport services, offered to attend medical appointments with patients or were involved with committees on health (Figure 3.03.6). Around half of services provided homelessness support and aged care services.

Screening programs

- In 2010–11 most services offered screening programs. Between 70% and 80% offered services in diabetic screening, PAP smear/cervical screening, regular well persons checks, hearing screening, sexually transmissible infection screening and eye screening. Sixty-eight per cent provided cardiovascular screening and 56% offered renal screening. (Figure 3.03.7).

Traditional health care

- In 2010–11, around 20% of Indigenous primary health-care services offered bush tucker nutrition programs or traditional healing, 12% provided bush medicine programs and 4% offered other traditional health care programs (Figure 3.03.8).

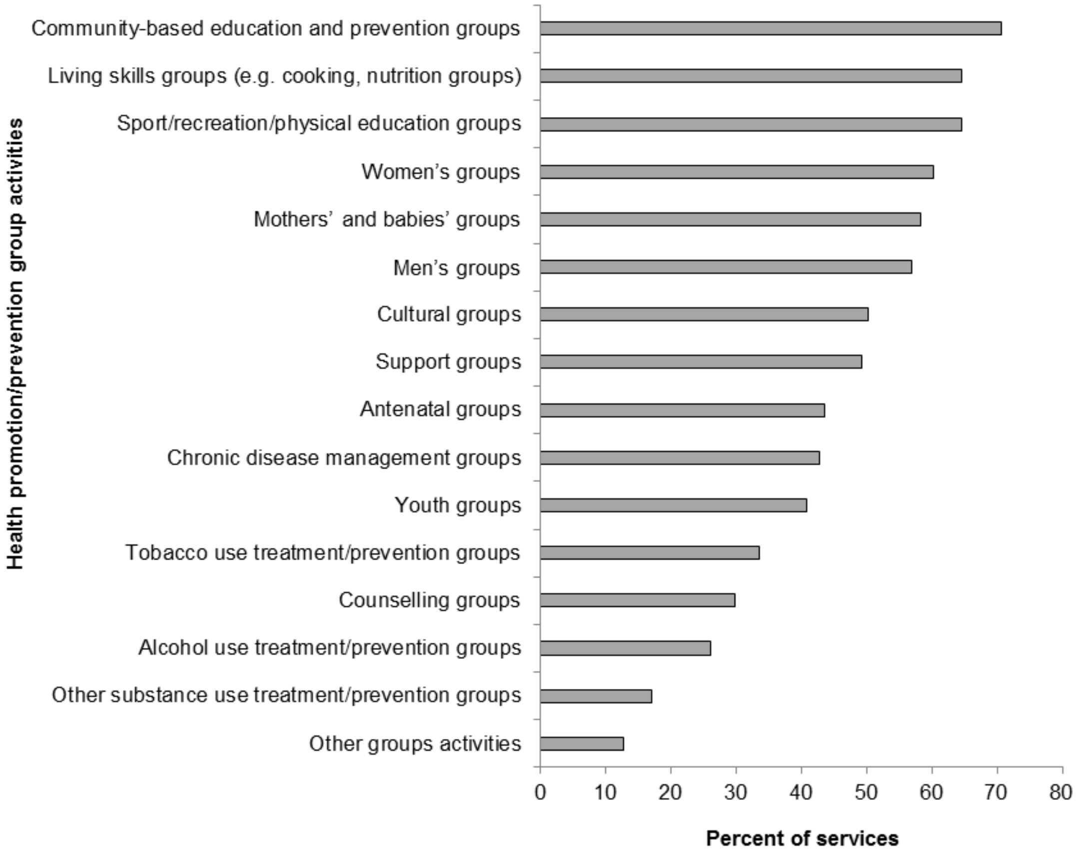
Health promotion/prevention group activities

- In 2010–11, the most common health promotion/prevention group activity run by Aboriginal and Torres Strait Islander primary health-care services was community based education and prevention groups (71%), followed by living skills groups (e.g. cooking and nutrition groups) and sport/recreation/physical education groups (each 65%) and women's groups (60%) (Figure 3.03.9).
- The least common health promotion/prevention group activities were alcohol use groups (26%) and other substance use groups (17%).



(a) One hundred and eighty of the 205 respondent Aboriginal and Torres Strait Islander primary health-care services provided information on group activities offered by the service. The percentages in the table above are calculated as a proportion of these 180 services.

Figure 3.03.9: Proportion(a) of Aboriginal and Torres Strait Islander primary health-care services that ran health promotion/prevention group activities during 2010–11

Substance use services

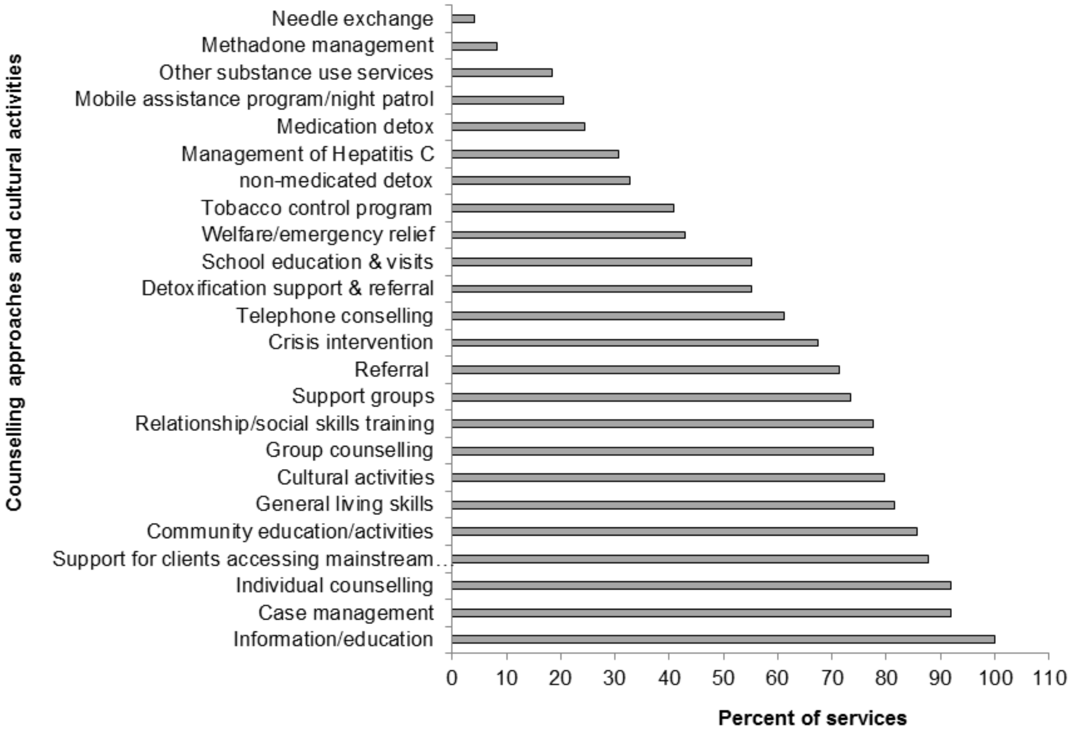
In 2010–11, there were 51 stand-alone Indigenous-specific substance use services that received OATSIH funding, of which 49 (96%) responded to the OSR questionnaire.

Counselling approaches and cultural activities

- In 2010–11, information/education programs were the most common program offered by substance use services (100%), followed by individual counselling and case management programs (each 91%) (Figure 3.03.10; Table 3.03.12).
- Methadone management (8.2%) and needle exchange programs (4.1%) were the least offered programs.

Other selected group programs

- In 2010–11, the most commonly run group programs by substance use services were cultural groups (85%), community-based education and prevention groups and living skills groups (each 83%) and alcohol use treatment/prevention groups (81%) (Figure 3.03.11; Table 3.03.13).
- Less than half of substance use services ran youth groups (34%).



(a) All of the 45 respondent Aboriginal and Torres Strait Islander substance use services provided valid data about activities the service provided to tackle substance use.

Additional information

Information on Indigenous primary health care services funded through the Health for Life (HfL) program that had health promotion programs for behavioural risk reduction is available from the AIHW's Healthy for Life data collection.

- In 2009–10, 81% of HfL funded services had community health promotion or development activities aimed at preschools or schools, and between 60% and 70% had programs involving men's groups, women's groups, community councils, or child care services or play groups (Table 3.03.14).
- Most HfL funded services provided strategies for chronic disease prevention, including brief intervention smoking and alcohol reduction strategies, nutrition and physical activity strategies and strategies aimed at emotional well-being (each offered by around 90% of services) (Table 3.03.15).
- Between 80% and 90% of HfL funded services offered chronic disease management strategies, including strategies relating to smoking and alcohol use, nutrition, physical activity and emotional well-being in 2009–10 (Table 3.03.16).

Data quality issues

Health Expenditure Data

Health expenditure data is affected by most of the reservations about data relating to Aboriginal and Torres Strait Islander people. The issue of poor Indigenous identification means that the attribution of expenditure to Indigenous people either on a population or per capita basis must be treated with caution. This single factor is arguably the most important data quality issue, affecting as it does nearly all health and population based measures. Reliable Indigenous status data is a major requirement to produce reliable, consistent and valid information on most aspects of Indigenous health. The “completeness of identification of Indigenous Australians varies significantly across states and territories” and in administrative health data collections (SCRGSP 2006).

For many publicly funded health services, there is incomplete information available about service users and, in particular, about their Indigenous status. For privately funded services, this information is frequently unavailable. For those services that do collect this information, recording Indigenous status accurately for all people does not always occur. The result is that there is some margin of error in the estimations of health expenditure for Indigenous people and their corresponding service use.

Expenditure estimates

There may be some limitations associated with the scope and definition of health expenditures included in this measure. Other (non-health) agency contributions to health expenditure, such as ‘health’ expenditures incurred within education departments and prisons, are not included.

In some areas of expenditure, surveys have been used to estimate service use by Indigenous people, which, in turn, have been used in the estimates of expenditure. Consequently, the reliability of the expenditure estimates is affected by sampling error.

Furthermore, although every effort has been made to ensure consistent reporting and categorisation of expenditure on health goods and services, in some cases there may be inconsistencies across data providers. These may result from limitations of financial reporting systems, and/or different reporting mechanisms (AIHW 2009).

Under-identification

Estimates of the level of Indigenous under-identification were used to adjust some reported expenditure. In some states and territories, a single state wide average under-identification adjustment factor was applied. In others, differential under-identification factors were used, depending on the region in which the particular service(s) were located. In some jurisdictions, no Indigenous under-identification adjustment was considered necessary.

Comparison with estimates for 2004–05

The definition of health expenditure changed in 2007, when high care residential aged care services were reclassified as welfare services. Prior to this point, residential aged care expenditure was divided with high care residential aged care expenditure being classified as health and low care residential aged care expenditure classified as welfare services.

This indicator provides separate estimates of expenditure for health, and for health and high care residential aged care services. This allows comparison with estimates with health and high care residential aged care expenditure in the 2004–05 report as well as presentation of estimates that relate more directly to estimates in the AIHW’s Health expenditure Australia 2007–08 (AIHW 2009). There has also been a change in the method for estimating MBS and PBS expenditure. For the first time in 2006–07, Medicare Voluntary Indigenous Identifier (VII) data was used to estimate expenditure on Indigenous people for

Medicare services. Services include general practitioner (GP), specialist, pathologist and imaging services, and prescription pharmaceuticals provided to Aboriginal and Torres Strait Islander people (see Appendix B for more details). Prior to this, data from the Bettering the Evaluation and Care of Health (BEACH) survey data were used in these estimates. This change may have contributed to the increase in estimated MBS and PBS expenditure reported in 2006–07 compared with 2004–05.

General Practitioner Data (BEACH)

Information about general practitioner encounters is available from the Bettering the Evaluation and Care of Health (BEACH) survey. The BEACH data on Indigenous Australians should be treated with care. First, the sample has not been designed to produce statistically significant results for population subgroups such as Indigenous Australians. Second, the identification of Indigenous Australians is not complete. Although the questionnaire contains an Indigenous identifier, it is unknown whether all GPs ask their patients this question. In the BEACH survey, 'not stated' responses to the Indigenous identification question are often higher than the 'yes' responses. It can be assumed, therefore, that the survey consistently undercounts the number of Indigenous Australians visiting general practitioners. Further detailed analyses of this issue are covered in General practice in Australia, heath priorities and policies 1998 to 2008, (Britt & Miller 2009:101):

'The findings of a BEACH substudy confirmed this suspected under-identification. In the data period reported here, 1.4% of patients encountered identified themselves as Indigenous. In contrast, in a BEACH substudy that asked 9,245 patients a complete set of questions about their cultural background (including Indigenous status) 2.2% (95% CI: 1.6–2.9) of respondents identified themselves as Indigenous (Britt et al. 2007). This rate is similar to the ABS estimates of Indigenous Australians as a proportion of the total population (ABS 2006).

However, the BEACH substudy included Indigenous Australians seen at Community Controlled Health Services funded through Medicare claims, and the estimate of 2.2% could have been an overestimate for the proportion of encounters that are with Indigenous patients in general practice as a whole. Deeble et al. (2008) conducted further investigations on this data and estimated that the BEACH encounter identification was an underestimate of about 10%, and that a more reliable estimate of the Indigenous population would be about 1.6% of all encounters (Deeble et al. 2008).

The findings of these studies are that some GPs are not routinely asking patients at the encounter about their Indigenous status, even when this is a variable specifically collected for each patient encountered, as it is in BEACH encounter data.'

Healthy for Life data

For the July 2008 to June 2009 reporting period, 72 services submitted data as part of the Healthy for Life Program.

Services started submitting their data through an electronic interface (OSCAR) for the February 2008 reporting period. This has improved the quality of data submitted.
Not all of the services were able to provide data for all of the essential indicators and service profile questions. The number of services that were able to provide data varies across the qualitative and quantitative indicators.

Community Housing and Infrastructure Needs Survey (CHINS)

The 2006 CHINS collected information on a variety of topics from discrete Aboriginal and Torres Strait Islander communities throughout Australia and on Indigenous organisations that provide rental housing to Indigenous people. In 2006, CHINS information was collected on 496 Indigenous organisations, which managed a total of 21,854 permanent dwellings. The majority of those dwellings were located in the Northern Territory (6,448), Queensland (6,230), New South Wales (4,176) and Western Australia (3,462) (ABS 2007).

The CHINS survey covers only discrete Indigenous communities. In 2006, the CHINS collected information from 1,187 discrete indigenous communities. This included approximately 92,960 Aboriginal and Torres Strait Islanders or 18% of the total Indigenous population. CHINS data is collected every 5 years. The data are collected from key personnel in Indigenous communities and housing organisations that are knowledgeable about housing and infrastructure issues.

The estimates are not subject to sampling error because the CHINS was designed as a complete enumeration of discrete Indigenous communities. However, data could not be obtained from a small number of communities. In addition, the community population was often estimated by community representatives without reference to records. Therefore, the data is subject non-sampling error.

Further information on the CHINS can be found in the publication Housing and infrastructure in Aboriginal and Torres Strait Islander communities (ABS 2007).

OATSIH Service Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012).

List of Tables

List of figures

3.04 Early detection and early treatment

The early detection and early treatment of disease among the Indigenous population measured by the health assessment and disease screening of Aboriginal and Torres Strait Islander people

Data sources

Data for this measure come from the Medicare database, the AIHW BreastScreen Australia database, the National Bowel Cancer Screening Register, the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS), the AIHW's National Mortality Database, and the OATSIH Services Reporting Data Collection which replaces the Service Activity Reporting (SAR) database.

Medicare database

Medicare enrolment application forms are lodged by persons wishing to enrol with Medicare at Medicare offices in each state/territory or by mail. Information from these forms is entered directly into the Medicare database, which is held by the Department of Health and Ageing (DoHA).

In November 2002, the ABS standard question on Indigenous identification was included on this form. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete.

As at 1 May 2012, 339,310 Indigenous Australians were enrolled on the VII database. This represents 59% of the estimated total Indigenous population (AHMAC 2012).

Medicare data presented in this report have been adjusted for under-identification. There are a number of caveats to the VII adjustment methodology, including that as the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could therefore be biases in the data that are not addressed by the adjustment methodology.

BreastScreen Australia

BreastScreen Australia is a comprehensive population-based screening program for breast cancer. It consists of a network of dedicated screening and assessment services throughout urban, rural and remote areas of all states and territories. The program provides free biennial mammographic screening and follow-up of any suspicious lesions identified at screening to the point of diagnosis. It is aimed specifically at asymptomatic women aged 50–69 years, with a participation target of 70%. However, women aged 40–49 years and 70 years and older are able to attend for screening (AIHW 2010a).

The national program was established in 1991. It is a joint program of the Australian Government and state and territory governments. BreastScreen Australia is monitored annually and reported at the national level by the AIHW in the "BreastScreen Australia monitoring report".

National Bowel Cancer Screening Register

The National Bowel Cancer Screening Program (NBCSP) was implemented in August 2006 by the Australian Government, in partnership with state and territory governments, as part of its Strengthening Cancer Care initiative. The goals of the NBCSP are to reduce the incidence of and mortality due to bowel cancer through screening to detect abnormalities of the colon and rectum at an early stage. Furthermore, where bowel cancer has developed, to detect cancers at an early stage in order to maximise the effectiveness of treatment (AIHW & DoHA 2009).

Phase 1 of the NBCSP began in August 2006, where people across Australia turning 55 or 65 years of age between 1 May 2006 and 30 June 2008 were invited to screen for bowel cancer. Phase 2 was introduced in July 2008 and expanded the program so that people turning 50, 55 or 65 years of age between 1 January 2008 and 31 December 2010 were invited to screen. Invitation packs, including a faecal occult blood test (FOBT), were sent directly to participants by Medicare Australia. Data are collected about participants and their screening outcomes from a variety of sources and stored in the National Bowel Cancer Screening Register, which is maintained by Medicare Australia. The data are collected on questionnaires completed by participants, general practitioners, colonoscopists, pathologists and other specialists. The AIHW produces annual monitoring reports for DoHA to assist in management of the NBCSP.

Data in this indicator are based on data recorded in the Register for the eligible Phase 2 population invited between 1 July 2008 and 30 June 2011, and include participation and PHCP follow-up activity until 30 June 2011.

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

OATSIH Services Reporting data collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Analyses

Medicare Benefits Schedule health assessments/checks

Over the last few years, the Australian Government has introduced a number of new Indigenous health checks and health assessments within the Medicare Benefits Schedule (MBS) to help improve early intervention and diagnosis for treatable conditions. The MBS now provides items specifically for regular health checks or assessments for Aboriginal and Torres Strait Islander people of all ages.

A health assessment includes an assessment of a patient's health and physical, psychological and social function and whether preventative health care and education should be offered to the patient. The assessment also includes keeping a record of the health assessment and offering the patient a written report about the health assessment, with recommendations about matters covered.

Data on child and adult health assessments come from the Medicare Database. The Medicare database includes information on the number of health assessments for Indigenous and non-Indigenous Australians of different ages. From May 2010, the previous Aboriginal and Torres Strait Islander Health Check MBS items 704, 706, 708 and 710 were reclassified as MBS item 715.

- For the period July 2010 to June 2011, there were 22,415 health assessments of Indigenous children in Australia (a rate of 113 per 1,000 Indigenous children) (Table 3.04.1). The rate at which Indigenous children aged 0–14 years received health assessments under the MBS ranged from 16 per 1,000 in Tasmania to 169 per 1,000 in the Northern Territory.
- Between July 2010 and June 2011, there were 38,331 health assessments of Indigenous Australians aged 15–54 years, which was a rate of 120 per 1,000 population. The rate at which Indigenous Australians aged 15–54 years received health assessments under the

MBS ranged from 28 per 1,000 in Tasmania to 159 per 1,000 in the Northern Territory (Table 3.04.1).

- Between July 2010 and June 2011, there were 10,623 health assessments of Indigenous Australians aged 55 years and over (a rate of 209 per 1,000 population). The rate of MBS health assessments for Indigenous Australians aged 55 years and over ranged from 55 per 1,000 in Tasmania to 265 per 1,000 in the Northern Territory (Table 3.04.1).
- Between July 2010 and June 2011, Indigenous Australians aged 55 years and over received MBS health assessments at a rate of 209 per 1,000 (Medicare Item no. 715). This was lower than the rate at which all Australians aged 75 years and over received assessments during this period (271 per 1,000) (Medicare Item numbers 700/701/702/703/705/707) (Table 3.04.2).
- The rate of MBS health checks and health assessments for Aboriginal and Torres Strait Islander people have significantly increased since their introduction in 2006. Between the first quarter of 2006 and the fourth quarter of 2011, the rate of MBS health checks for Indigenous Australians aged 0–14 years increased from 9 per 1,000 to 134 per 1,000; the rate of MBS health assessments for Indigenous Australians aged 15–54 years increased from 29 per 1,000 to 146 per 1,000; and the rate of MBS health assessments for Indigenous Australians aged 55 years and over increased from 67 per 1,000 to 246 per 1,000 (Table 3.04.3 and Figure 3.04.1).
- There has also been a significant increase in health assessments for Indigenous Australians since the introduction of the National Partnership Agreement on Closing the Gap in Indigenous Health Outcomes in July 2008. Over the period July 2008 to December 2011, the rate of MBS health checks for Indigenous Australians aged 0–14 years increased by 101%; the rate of MBS health assessments for Indigenous Australians aged 15–54 years increased by 178%; and the rate of MBS health assessments for Indigenous Australians aged 55 years and over increased by 145% (Table 3.04.3 and Figure 3.04.1).

Table 3.04.1: Medicare Benefits Schedule health assessments and health checks for Indigenous Australians (MBS item 715) aged 0–14 years, 15–54 years and 55 years and over, by state/territory, 2010–11

(continued)

Table 3.04.3 (continued): Rate[(a)] of MBS health checks/assessments for Indigenous Australians (MBS item 715) aged 0–14 years, Indigenous Australians aged 15–54 years and Indigenous Australians aged 55 years and over, January–March 2006 to October–December 2011

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period January–March 2006 to October–December 2011.

(a) Number per 1,000 population.
(b) Average quarterly change determined using linear regression analysis.
(c) Per cent change between January–March 2006 and October–December 2011 based on the average quarterly change over the period.

Notes

1. Rates were calculated using the Indigenous population estimates for 2006–2011, divided by four to obtain quarterly rates for each year.
2. Item 715 commenced in May 2010, MBS codes 704, 706, 708 and 710 were reclassified as 715 for prior years.
3. Data 0–14 year olds for quarter 1, 2006 was not available.

Source: AIHW analysis of Medicare data.

Breast cancer screening

BreastScreen Australia—which is jointly funded by the Australian, state and territory governments—undertakes nationwide breast cancer screening. It targets women aged 50–69 years for screening once every 2 years. The program aims to have 70% or more of women aged 50–69 years participating in screening over a 24-month period. All recruitment activities undertaken by BreastScreen Australia specifically focus on women in this age group, although women aged 40–49 years and those over 70 years may also use the service. When making direct comparisons between the eight states and territories it is important to consider the substantial differences that exist between the jurisdictions, including population, area and geographic structure.

- Of the 1,319,771 women aged 50–69 years who participated in screening through BreastScreen Australia in 2008–09, 10,902 (0.8%) identified as Aboriginal or Torres Strait Islander (AIHW 2011).
- During 2008–2009, the participation rate for BreastScreen Australia was highest among those aged 60–64 years for Indigenous women (39%). The participation rate measures the proportion of the eligible population attending the screening program within a 24-month period (Table 3.04.4).
- The age-standardised participation rate for Indigenous women aged 50–69 years was 37%, which was markedly lower than the national rate for other women in that age group (56%). The participation rate for Indigenous women aged 40 years and over was also lower than for other women in that age group (25% compared with 33% for all women) (Table 3.04.4).
- The breast screening participation rates for Indigenous women (excluding those in Tasmania and the Australian Capital Territory) aged 50–69 years ranged from 28% in Victoria to 49% in Queensland (Table 3.04.4). Age standardised rates for women aged 50–69 are not available for Tasmania and the Australian Capital Territory as Indigenous population estimates are not available for this age group.
- The participation rate for Indigenous women aged 50–69 years ranged between 35% to 37% for all years between 1999–2000 and 2008–2009. Over the same period, the participation rate for other women ranged between 55% and 57% (Table 3.04.5; Figure 3.04.2).

Care needs to be taken when comparing Indigenous and non-Indigenous participation rates owing to under-identification of Indigenous women in the BreastScreen Australia program.

Caution also needs to be taken in comparing data across jurisdictions, given differences in the collection of data by Indigenous status across jurisdictions and small numbers.

Breast cancer mortality

Data have been combined for the 5 year period 2006–2010 due to the small number of Indigenous deaths from breast cancer each year.

- In 2006–2010, the age-standardised breast cancer mortality rate for Indigenous women of all ages in New South Wales, Queensland, Western Australia, South Australia and the Northern Territory combined was 26.3 per 100,000 women. This was 1.2 times the age-standardised breast cancer mortality rate for non-Indigenous women (see Table 1.08.4 of Indicator *1.08 Cancer* of this report).

Table 3.04.4: Age-specific participation rates[(a)] in BreastScreen Australia programs of Indigenous and other women, by state/territory, 2008–2009

(continued)

Table 3.04.4 (continued): Age-specific participation rates[(a)] in BreastScreen Australia programs of Indigenous and other women, by state/territory, 2008–2009

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 1999–2000 to 2008–2009.

(a) Rates are the number of women screened as a percentage of the eligible female population calculated as the average of the 2007 and 2008 ABS estimated resident population.
(b) Rates are directly age-standardised to the Australian 2001 standard population.
(c) Rate ratio Indigenous: other women.
(d) Rate difference is age-standardised rate for Indigenous women divided by age standardised rate for other women.

Note: Other women includes women in the 'not stated' category for Aboriginal and Torres Strait Islander status.

Bowel cancer screening

The National Bowel Cancer Screening Program (NBCSP) aims to reduce the incidence of illness and mortality related to bowel cancer in Australia through screening to detect cancers and pre-cancerous lesions in their early stages in order to maximise the effectiveness of treatment. Data in this indicator are based on data recorded in Phase 2 of the NBCSP Register (ran between 1 July 2008 and 30 June 2011) for people turning 50, 55 or 65 between 1 January 2008 and 31 December 2010 who were invited to screen for bowel cancer. During Phase 2, the program was suspended for about six months after the screening test was found to be returning a higher rate of negative results than expected. Remediation actions to retest those who may have been affected were undertaken and the apparent effects are also presented in the NBCSP monitoring report (AIHW 2012).

Participation in screening

- Between 1 July 2008 and 30 June 2011, 2,097,520 eligible Australians were invited to screen for bowel cancer and 806,480 (38%) had participated by 30 June 2011.
- There were 4,825 people (0.6%) who identified as Indigenous who responded to the invitation to screen. This is lower than the eligible population who reported as Indigenous at the time of the 2006 Census (1.3%) (Table 3.04.6).
- Of Indigenous people who participated in the program, 2,109 were aged 50 years, 1,693 were aged 55 years and 1,023 were aged 65 years (Table 3.04.6).

Table 3.04.6: People responding to the National Bowel Cancer screening invitations, by age, sex and Indigenous status, 2010

Total	**4,825**	**0.6**	**766,173**	**99.4**	**770,998**	**1.3**	**98.7**

Notes

1. NBCSP percentages equal the number of people identifying as either Indigenous or non-Indigenous as a proportion of all participants who indicated their Aboriginal and Torres Strait Islander status.
2. Participants who did not indicate Aboriginal and Torres Strait Islander status were recorded as 'Not stated', these participants have been excluded from this analysis.
3. The total number of not stated were 18,343 male, 17,139 female, 35,482 persons.
4. Indigenous status proportions as recorded at the 2006 Australian Census of Population and Housing are included for comparative purposes.
5. There were 35,511 people (5.2%) who did not indicate the Indigenous status on the Census, these have been excluded from the 2006 Census columns.

Source: AIHW & DoHA 2012.

Faecal Occult Blood Test (FOBT) positivity numbers and rates

There were 2,097,520 eligible people invited to screen in Phase 2 of the NBCSP, and by 30 June 2011, 806,480 participants had returned at least one completed FOBT kit. Of these, 794,454 (98.5%) had a correctly completed FOBT kit tested by the pathology laboratory. Those participants recorded as having inconclusive or incorrectly completed FOBT kits were requested to complete another FOBT, but some had not returned a correctly completed the kit by 30 June 2011(AIHW 2012).

Only correctly completed FOBT kits were analysed. If no significant blood is found in either of the samples, the FOBT result is negative. If significant levels of blood are present in at least one of two samples, the FOBT result is considered positive. The Phase 2 positivity rate was higher than in previous NBCSP monitoring reports and this may be related to the different kits used within Phase 2, retesting as part of remediation actions in Phase 2, or other unknown factors (AIHW 2012).

- Positivity rates were higher in people identified as Indigenous (11%) than non-Indigenous (8%); and this difference was statistically significant (Table 3.04.7).
- There was an increase in the FOBT positivity rate with an increase in age for both Indigenous males and females. The positivity rate of males who participated was higher than that of females, indicating both age and sex affect the FOBT positivity rate (Table 3.04.7).

Colonoscopy procedures

The table 3.04.7 also provides summary information on the number of colonoscopies as part of the NBCSP.

Only 42,580 of the 59,034 participants who underwent a colonoscopy by 31 January 2011 had their Indigenous status recorded, so comparisons of colonoscopy follow-up rates between Indigenous and non-Indigenous people should be made with caution.

- Colonoscopy follow-up rates were significantly lower for Indigenous people (58%) than non-Indigenous people (72%) (Table 3.04.7).

Table 3.04.7: FOBT positivity rates from national bowel screening and Crude colonoscopy follow-up after a positive FOBT result, by age, sex and Indigenous status, 2010

(continued)

Table 3.04.7 (continued): FOBT positivity rates from national bowel screening, by age, sex and Indigenous status, 2010

* Represents results with statistically significant differences in the Indigenous/other comparisons at the $p < 0.05$ level.

(a) Rate difference is equal to the Indigenous rate minus the non-Indigenous.
(b) Rate ratio is equal to the Indigenous rate divided by the non-Indigenous rate.

Notes

1. Indigenous status was defined by the participant on the Participant Details form.
2. There were 3,033 recorded colonoscopies and 34,210 positive FOBT results where Indigenous status was not stated. These are regarded as missing data and are excluded from this table. Hence the sum of the areas may be less than the national total.
3. Percentages of colonoscopies performed equal the number of people who have had a colonoscopy recorded following a positive FOBT as a proportion of the total number of people with positive FOBT results.
4. As progression through the pathway to the colonoscopy stage may take some time, some participants (particularly those aged 50 years) may not have had sufficient time to undergo a colonoscopy. Additionally, reporting of colonoscopy follow-up is not mandatory. Therefore, actual numbers of participant colonoscopies may be underestimated.

Source: National Bowel Cancer Screening Program Register as at 21 July 2011.

Mortality from bowel cancer

- In 2006–2010, the age-standardised mortality rate of bowel cancer was 17 per 100,000 for Indigenous males and 12.3 per 100,000 for Indigenous females (see Table 1.08.4 in the Indicator *1.08 Cancer* of this report).
- In 2007, the risk of dying from bowel cancer by the age of 85 was 1 in 33 for males and 1 in 50 for females (1 in 41 for persons) (AIHW 2012).

Cervical cancer screening

A cervical cancer may take 10 or more years to develop, but before this, the cervical cells may show pre-cancerous changes. These early changes can be detected by a pap smear and, if they are promptly treated, cervical cancer can be prevented. Self-reported data from the NATSIHS on the occurrence and regularity of pap smears among Aboriginal and Torres Strait Islander women are presented in the tables and figure below.

- In 2004–05, approximately 85% of Indigenous women aged 18 years and over reported ever having a pap smear test and 58% reported having regular pap smear tests (Table 3.04.8).

Pap smears by age

- The 25–34 and 35–44 year age groups had the highest proportion (both 68%), and the 18–24 and 55 years and over age groups had the lowest proportion (both 43%) of Indigenous women who reported having regular pap smear tests (Table 3.04.8).

Table 3.04.8: Indigenous women aged 18 years and over reporting whether had a pap smear test[(a)], by age group, 2004–05

Pap smears by state/territory

- In 2004–05, the proportion of Indigenous women who reported never having had a pap smear test was highest in Western Australia (16%) and lowest in Victoria (11%) (Table 3.04.9).
- The proportion of Indigenous women who reported having regular pap smear tests was highest in the Northern Territory (72%) and lowest in New South Wales and Western Australia (both 52%).

Pap smears by remoteness and time series

- In 2004–05, the proportion of Indigenous women who reported never having had a pap smear test was lowest in *Inner regional* areas (7%) and highest in *Major cities* and *Outer regional* areas (both 15%) (Table 3.04.10).
- The proportion of Indigenous women who reported having regular pap smear tests was highest in *Remote and very remote* areas (65%) and lowest in *Major cities* (54%).
- Over the period 2001 to 2004–05, the proportion of Indigenous women who reported having regular pap smear tests increased in remote areas (from 56% to 65%) and decreased in non-remote areas (from 52% to 47%) (Figure 3.03.3).

Figure 3.04.3: Indigenous women aged 18 years and over who had regular pap smear tests, by remoteness, 2001 and 2004–05

Mortality from cervical cancer

Data on the mortality of Indigenous women from cervical cancer are presented below.

- Over the period 2006–2010 in New South Wales, Queensland, Western Australia, South Australia and the Northern Territory combined, there were 58 deaths of Indigenous women from cervical cancer. The age-standardised rate of cervical cancer for Indigenous women was 8.8 per 100,000. This was 4.6 times the rate for non-Indigenous women (see Table 1.08.4 in the Indicator *1.08 Cancer* of this report).
- In 2003–2007, the age-standardised mortality rate of cervical cancer for Indigenous women aged 50–69 years, which is the target age for cervical cancer screening, was 8.3 per 100,000 compared with 2.0 per 100,000 for non-Indigenous women of the same age (AIHW 2010b).

Other screening activities

The OSR includes data on health-related activities undertaken or facilitated by Aboriginal and Torres Strait Islander primary health-care services, including a range of screening programs.

- In 2010–11, approximately 75% of respondent Aboriginal and Torres Strait Islander primary health-care services provided well persons checks, 76% provided pap smear/cervical screening and 80% provided diabetic screening (Table 3.04.11).
- Between 2001–02 and 2010–11, there was a significant increase in the proportion of Aboriginal and Torres Strait Islander primary health-care services providing cardiovascular screening (27% over this period), renal disease screening (19%), well person's checks (19%) and STI screening (12%) (Table 3.04.11).

Table 3.04.11: Percentage of respondent Aboriginal and Torres Strait Islander primary health-care services providing screening activities, 2001–02 to 2010–11

	2001–02	2002–03	2003–04	2004–05	2005–06	2006–07	2007–08	2008–09	2009–10	2010–11[(a)]	Per cent change[(c)]	Annual growth[(b)]

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 2001–02 to 2010–11.

(a) Two hundred and thirty-four of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data about health related activities provided by the service for 2010–11. The percentages in the table above are calculated as a proportion of these 234 services.

(b) Average annual change in percentage of respondent Aboriginal and Torres Strait Islander primary health-care services providing screening activities determined using linear regression analysis.

(c) Per cent change between 2001–02 and 2010–11 based on the average quarterly change over the period

Note: Since 2008–09 OSR data counts all auspice services individually when calculating rates, therefore caution should be exercised when comparing rates with earlier data collection periods.

Additional information

Studies on early detection, diagnosis and survival rates for cancer in Indigenous Australians

There have been a number of studies that have investigated the stage of diagnosis and survival rates for cancer for Indigenous Australians.

A landmark study by Condon et al. (2005) on the stage at diagnosis and cancer survival of Indigenous and non-Indigenous people in the Northern Territory between 1991 and 2000 found that Indigenous people were more likely than non-Indigenous people to be diagnosed with advanced disease for cancers of the colon and rectum, breast, cervix and non-Hodgkin's lymphoma. The difference in the proportion of people diagnosed with localised disease ranged from 13 percentage points for cervical cancer (Indigenous 63% compared with non-Indigenous 76%) to 29 percentage points for non-Hodgkin's lymphoma (6% compared with 35%). However, for cancer of the lung, Indigenous people were more likely to be diagnosed with localised disease (41% compared with 31%)—possibly because many older Indigenous people have regular chest X-rays for clinical management of chronic respiratory disease and as part of contact-tracing and long-term follow-up by the tuberculosis control program.

Indigenous people had lower cancer survival than non-Indigenous people for all five cancer sites. The difference in age-stage-adjusted 5-year survival rates was greatest for non-Hodgkin's lymphoma (Indigenous 16% compared with non-Indigenous 65%) and least for lung cancer (5% compared with 12%). With few exceptions, Indigenous people had lower survival than non-Indigenous people with the same stage at diagnosis for each cancer site. The relative risk of cancer death (Indigenous compared with non-Indigenous) was greater for people diagnosed at younger than older age for cancers of the colon and rectum, lung and breast, but not for cervical cancer or non-Hodgkin's lymphoma. For colorectal and lung cancers, the relative risk was greater for people diagnosed with localised compared with advanced disease; this was not the case for the other three cancer sites.

Overall, the relative risk of cancer death was higher for Indigenous than non-Indigenous patients regardless of stage of diagnosis or cancer type (Condon et al. 2005).

In relation to the cancer survival differential, it is relevant to note that the 'absolute difference in cancer survival is greatest for cancers with the highest survival in non-Indigenous people—cancers of the thyroid, breast, prostate and bowel. For cancer of the thyroid, 5-year survival for all Australian cases is over 90% and for breast cancer over 80%, compared with only 60% and 42%, respectively, for Indigenous cases in the Northern Territory. These cancers are amenable to early diagnosis, effective treatment and a high probability of cure. Better access to, and higher quality of, health care offers the possibility of disease cure for many Indigenous people with these cancers' (Condon 2004).

A study examined the role of stage of diagnosis in cancer for 815 Indigenous and 810 non-Indigenous patients diagnosed with cancer in Queensland between 1997 and 2002. It found that, after adjustment for stage at diagnosis, treatment and comorbidities, non-Indigenous Australians had better survival than Indigenous patients (hazard ratio = 1.3, 95% CI 1.1–1.5). The stage at diagnosis was significantly different, with 47% of Indigenous patients with localised cancers compared with 53% of non-Indigenous patients. Comorbidities such as diabetes or chronic renal disease were more common in Indigenous patients. Indigenous patients were less likely to have had treatment for cancer (surgery, chemotherapy or radiotherapy) and waited longer for surgery (hazard ratio = 0.84, 95% CI 0.72–0.97) than non-Indigenous patients (Valery et al. 2006).

Exploring the experience of Indigenous people and their outcomes in relation to cancer incidence, stage of disease at presentation, access to treatment, survival and mortality can help illustrate aspects of Indigenous Australians' access to, and interaction with, the health system. This provides an opportunity to monitor health system performance for Indigenous Australians in relation to both primary care and specialist services, and the interaction between them (Condon 2004).

Data quality issues

Medicare data

MBS items

The MBS items included in this measure have been introduced over the last few years with the child health check item commencing in May 2006. The take-up of new MBS items is influenced by the speed at which practitioners and the population become aware of the new items and how to use them. Also take-up can be influenced by administrative processes and the time taken to change computer systems to incorporate these new items.

Standard Indigenous status question

In November 2002, the ABS standard question on Indigenous identification was included on Medicare enrolment forms. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Under-identification

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete. There were around 339,310 people who had identified as Aboriginal and/or Torres Strait Islander in this database at May 2012; around 59% of the estimated Aboriginal and Torres Strait Islander population (AHMAC 2012). There has been a rapid expansion in the number of enrolees who identified as Aboriginal and/or Torres Strait Islander, from 47,200 people in August 2004.

Readers should note the following caveats to the Medicare voluntary Indigenous Identifier (VII) adjustment methodology:

- Estimates generated by the adjustment methodology for a given period will vary according to the point in time at which they are calculated, as the adjustment factors will be updated regularly to account for the ongoing change in the population coverage of the VII sample.
- There are inherent uncertainties in the current ABS Indigenous population estimates, and they are therefore described by the ABS as 'experimental estimates and projections'. The ABS Indigenous population estimates after 2006–07 are experimental projections, based on a number of assumptions about future levels of fertility, mortality and migration. The projections are not predictions or forecasts, but are illustrations of the growth and change in population that would occur if these assumptions were to prevail over the projection period. There can be no certainty that any particular outcome will be realised, or that future outcomes will necessarily fall within the projected ranges.
- The propensity to identify as Aboriginal and/or Torres Strait Islander varies according to the motivations of the individual and the perceived uses of the data in question. For example, it is possible that there are some Aboriginal and Torres Strait Islander people who are registered with the VII but who do not identify as Indigenous for the purposes of the Census, or vice versa.
- In some areas, particularly remote and very remote areas, there is a portion of the Indigenous population that does not ever use the Medicare system. It is therefore possible that the adjustment methodology could overestimate Medicare use by the Indigenous population.

- As the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could be biases in the data that are not addressed by the adjustment methodology.

BreastScreen Australia

State and territory BreastScreen registers collect information on all breast cancer screening undertaken as part of BreastScreen Australia.

Women who attend for a screening mammogram at a BreastScreen Australia service are asked to complete a form that includes personal and demographic details, as well as personal and family history of breast cancer. The form also includes a question on Aboriginal and Torres Strait Islander status where women are able to identify as 'Aboriginal', 'Torres Strait Islander', 'both Aboriginal and Torres Strait Islander', or 'neither Aboriginal or Torres Strait Islander'. There is an additional 'not stated' category for women who choose not to answer this question. These responses are aggregated into the categories of 'Aboriginal and Torres Strait Islander', 'non-Indigenous' and 'not stated'. While self-reported data are generally a robust source of data on Aboriginal and Torres Strait Islander status (AIHW 2011), a significant cause of concern with the accuracy of these data is that some jurisdictions do not allow for the 'not stated' category. Further, some Aboriginal and Torres Strait Islander women may choose not to identify as such when presenting to a BreastScreen Australia service. Thus, some Aboriginal and Torres Strait Islander women may be incorrectly assigned non-Indigenous status. Indigenous status disaggregated by jurisdiction leads to very small numbers leading to issues around confidentiality and comparability.

Estimated resident populations and Indigenous experimental estimates and projections are provided by the ABS.

National Bowel Cancer Screening Register

Data on bowel cancer screening are available from the NBCSR by Indigenous status. Data are collected about participants and their screening outcomes from a variety of sources and stored in the Register. The data are collected on questionnaires completed by participants, GPs, colonoscopists, pathologists and other specialists.

Details of an invitee's Aboriginal and Torres Strait Islander status is not known at the time of invitation—these details are only collected if a person becomes a participant in the NBCSP and completes the relevant section of their Participant Details form. Hence, as the number of people invited into the NBCSP of these subgroups is not known, it is not possible to accurately determine their subsequent participation levels. Instead, the proportion of participants who reported their status within these subgroups is shown, along with the corresponding population proportions derived from those reported in the 2006 Census of Population and Housing. As the relevant subgroup questions on the NBCSP Participant Details form are worded identically to those in the Census, basic comparisons can be made. While it should be noted that proportions may have changed since the 2006 Census, these data allow two things to be determined:

1. Comparing the percentage of people who did not answer these questions (that is, those counted in the 'Not stated' columns) between the NBCSP participation data and the 2006 Census data provides an indication of the data quality.
2. If the data quality compared with the 2006 Census appears reasonable, an estimation of the level of participation of those within the subgroup can be made.

As the 'Not stated' percentages for questions related to Aboriginal and Torres Strait Islander status and disability status were similar between NBCSP participation data and the 2006 Census, it can be assumed that these questions were answered thoroughly for NBCSP participants (AIHW 2012). The proportion of participants who identified as Indigenous in the NBCSP was consistently lower than the comparable proportion who identified as Indigenous in the 2006 Census. This may have been due to:

1. The proportions of Indigenous and non-Indigenous people in the Australian population having changed slightly since the 2006 Census.
2. The eligible population who were Indigenous having participated at a lower rate than the eligible population who were non-Indigenous. That is, 0.6% of the eligible population who participated were reported as Indigenous, compared with 2.3% of the eligible population reporting as Indigenous at the time of the 2006 Census.

However, it should be noted that the proportion who did not respond to this question in the NBCSP was also consistently lower than in the 2006 Census.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The 2004–05 NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

OATSIH Services Reporting Data Collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. (The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012).

List of figures

3.05 Chronic disease management

The management of chronic disease among the Aboriginal and Torres Strait Islander population

Data sources

Data on chronic disease management come from Medicare, OATSIH Services Reporting data collection, the Healthy for Life data collection and Divisions of General Practice National Performance Indicators.

Medicare Database

Medicare enrolment application forms are lodged by persons wishing to enrol with Medicare at Medicare offices in each state/territory or by mail. Information from these forms is entered directly into the Medicare database, which is held by the Department of Health and Ageing (DoHA).

In November 2002, the ABS standard question on Indigenous identification was included on this form. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete.

As at 1 May 2012, 339,310 Indigenous Australians were enrolled on the VII database. This represents 59% of the estimated total Indigenous population (AHMAC 2012).

Medicare data presented in this report have been adjusted for under-identification. There are a number of caveats to the VII adjustment methodology, including that as the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could therefore be biases in the data that are not addressed by the adjustment methodology.

OATSIH Services Reporting data collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Healthy for Life

The Healthy for Life (HfL) program is an ongoing program funded by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) of the Australian Government Department of Health and Ageing (DoHA). The program aims to improve the capacity and performance of primary health-care services to deliver high-quality maternal, children's and chronic disease care to Aboriginal and Torres Strait Islander people. This is carried out through population health approaches using best-practice and quality improvement principles.

Services participating in the HfL program are required to submit de-identified, aggregate service data for 11 essential indicators. These indicators cover maternal health, child health and chronic disease care on a regular basis (6 and 12 months), as well as information about the characteristics of their service and organisational infrastructure.

The Commonwealth and the AIHW are working with the States and Territories to develop a national Key Performance Indicator (KPI) framework for Indigenous primary health care services. The new National KPIs will replace the *Healthy for Life* program Essential Indicators and cover maternal and child health and chronic disease management. The AIHW is leading the development and refinement of the indicators, data standards and analyses and reporting back to services. The national KPI data collection will be implemented in three stages, with rollout in 2012 and 2013.

Divisions of General Practice National Performance Indicators

Divisions of General Practice report on a set of National Performance Indicators (NPIs) as part of their accountability to their funding source. Data are submitted to DoHA (through the Primary Health Care Research & Information Service) and are reported annually in the Divisions Performance Indicator Reports. These provide a synthesis of the key findings related to specific NPIs using data derived from three main sources:

- The Divisions' 12 month reports.
- The characteristics and activities from the Annual Survey of Divisions (ASD).
- Medicare.

Analyses

MBS services claimed

Chronic disease management plans

From 1 July 2005, the Australian Government introduced chronic disease management Medicare items, including MBS items 721 and 723.

General Practitioner Management Plan (MBS item 721)

General Practitioner Management Plans (GPMPs) are for patients with a chronic or terminal medical condition who will benefit from a structured approach to management of their care needs. A rebate can be claimed once the patient's GP has prepared GPMP. The recommended frequency of GPMPs is once every 2 years. The GP may be assisted by their practice nurse, Aboriginal health worker or other health professional in the GP's medical practice or health service. The service must include a personal attendance by the GP with the patient.

Team Care Arrangement (MBS item 723)

Chronic disease management plans Team Care Arrangement (TCA) provide a rebate for a GP to coordinate the preparation of TCAs for a patient with a chronic or terminal medical condition who also requires ongoing care from a multidisciplinary team of at least three health or care providers. The recommended frequency is once every 2 years, supported by regular review services.

- Over the period 2009–10 to 2010–11 there has been an increase in the number of GP management plans (GPMP) and team care arrangements (TCA) claimed by Indigenous Australians (from 23,927 to 32,717 and from 18,680 to 26,525, respectively) (Table 3.05.1).
- Over the same period, there has also been an increase in allied health care services claimed through Medicare by Indigenous Australians with dental up from 77,343 to 122,822 and other allied health from 25,961 to 35,731 (Table 3.05.1).
- After adjusting for differences in age structures between the two populations, Indigenous Australians received more claimed GPMPs and TCAs than non-Indigenous Australians in 2010–11 (102 per 1,000 compared with 55 per 1,000 for GPMPS and 83 per 1,000 compared with 45 per 1,000 for TCAs) (Table 3.05.1).

Table 3.05.1: MBS services by selected categories claimed, by Indigenous status, Australia, 2009–10 and 2010–11

MBS services claimed	No. of services				Age standardised services per 1,000 population				Rate difference	
	Indigenous		Non-Indigenous		Indigenous		Non-Indigenous

Aboriginal and Torres Strait Islander primary health-care services

OATSIH Services Reporting

- In 2010–11, there were 235 respondent Aboriginal and Torres Strait Islander primary health-care services that provided information on their clinical health care activities. Not all services provide clinical care. Approximately 63% of the services had a doctor working at the service, with 362 full-time doctors in total (AIHW 2011).
- Approximately 83% of Indigenous primary health-care services provided management of chronic illness, 70% reported keeping track of clients needing follow-up (for example, through monitoring sheets/follow-up files), 74% reported they maintained health registers (for example, chronic disease register) and 75% used clinical practice guidelines. About 72% of Indigenous primary health-care services reported that they used Patient Information and Recall Systems (PIRS), which automatically provides reminders for follow-up and routine health checks (Table 3.05.2).
- Forty-three per cent of Indigenous primary health-care services provided chronic disease management groups, 58% provided chronic disease management groups relating to mothers and babies groups, 64% provided chronic disease management groups involving sport, recreation or exercise groups, 65% involving living skills groups and 57% involving men's groups (Table 3.05.2).
- There was a significant increase in the proportion of Indigenous primary health-care services providing management of chronic illness between 2001–02 and 2010–11 (from 74% to 85%) (Table 3.05.3; Figure 3.05.1). The proportion of services keeping track of clients needing follow-up fluctuated during this period but there was only a small annual increase over the period (0.1%) (Table 3.05.3).

Table 3.05.2: Percentage of respondent Indigenous primary health-care services providing chronic disease management activities and use of the Patient Information and Recall System, 2010–11

	Per cent
Chronic disease management activities[(a)]	
Management of diabetes	82.9
Management of cardiovascular disease	79.1
Management of other chronic illness	83.3
Keep track of clients needing follow-up (e.g. through monitoring sheets/follow-up files)	69.7
Maintains health registers (e.g. chronic disease register)	74.4
Clinical practice guidelines used (e.g. Central Australian Remote Practitioners Association, diabetes guidelines)	75.2
Patient Information and Recall Systems (PIRS)[(b)]	
PIRS which automatically provides reminders for follow-up and routine health checks	71.9
Chronic disease management groups[(c)]	
Counselling groups	29.9
Chronic disease management groups	42.7
Antenatal groups	43.6
Mothers and babies group	58.3

Women's groups	60.2
Youth groups	40.8
Other groups activities[(d)]	12.8

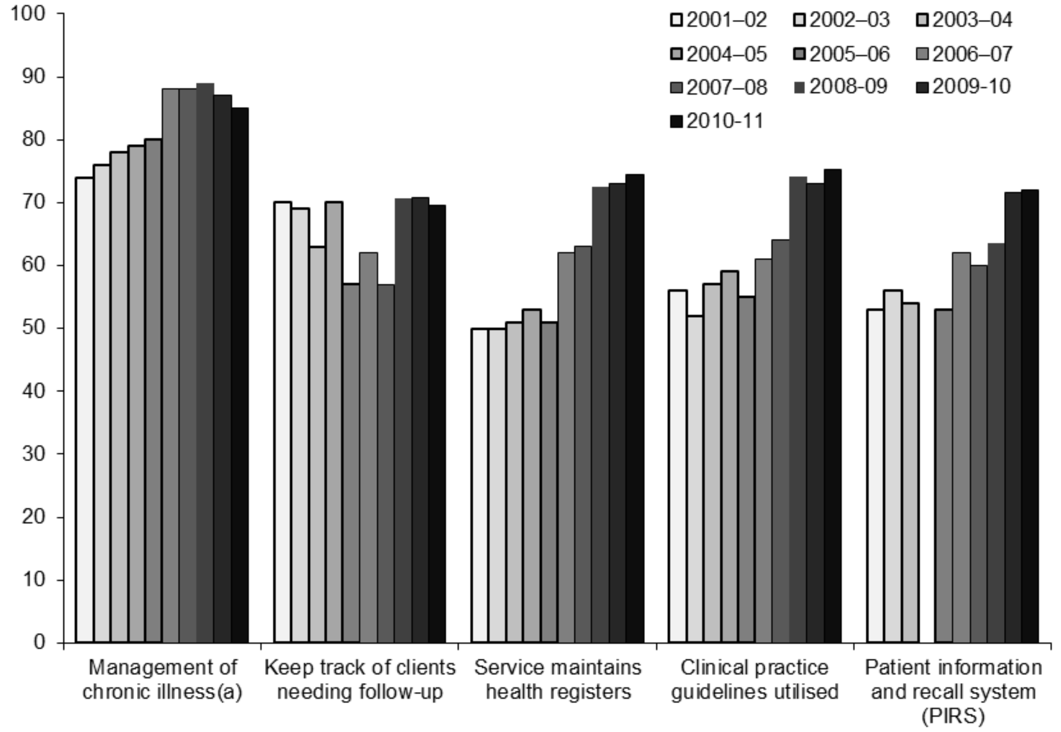
(a) Two hundred and thirty-four of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data about health related activities provided by the service for 2010–11. The percentages in the table above are calculated as a proportion of these 234 services.

(b) All of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data for using computers for 2010–11. The percentages in the table above are calculated as a proportion of these 235 services.

(c) Two hundred and eleven of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided information on group activities offered by the service. The percentages in the table above are calculated as a proportion of these 211 services.

(d) Other groups activities refer to other health group activities provided by respondent Aboriginal and Torres Strait Islander primary health care services.

Source: AIHW OSR data collection.



(a) From 2006–07 the OSR response category 'Management of chronic illness' was replaced by the three categories 'Management of diabetes', 'Management of cardiovascular disease' and 'Management of other chronic illness'. 'Management of chronic illness' represents the percentage of services that provided or facilitated access to any one of those three categories

Note: 2008–09 OSR data counts all auspice services individually when calculating rates, therefore caution should be exercised when comparing rates with earlier data collection periods.

Healthy for Life data

For the reporting period July 2008 to June 2010, 79 services that were funded through the Healthy for Life program provided data on chronic disease management (AIHW 2013)

In the period ending June 2010:

- Some of the most commonly used strategies for chronic disease management by HfL services included: behaviour risk reduction activities aimed at smoking, alcohol use, nutrition, physical activity and emotional wellbeing; the use of a condition register for recall and reminder; systematic follow-up of abnormal results; routine clinical reviews; hospital admission and discharge communications; and the provision of linkages, referrals and client advocacy, specifically in the areas of social services, housing, domestic violence and legal aid (Table 3.05.4).
- In relation to approaches to client self-management for clients with chronic disease, client education was the most commonly used strategy (85%), followed by goal setting (81%) and staff training (79%). There was an increase in the use of these strategies since the reporting period ending June 2007, where the proportions were 81%, 70% and 70%, respectively (Table 3.05.4).

Table 3.05.4: Chronic disease: management, reporting periods ending 30 June 2008, 2009 and 2010

Type II diabetes clients—HbA1c levels

HbA1c levels reflect the mean glycaemia over the preceding 2–3 months and the test is performed in accredited laboratories.

HbA1c levels are defined as:

a. Less than or equal to 7.0% (recommended level for diabetics)

b. Greater than 7.0% but less than or equal to 8.0%

c. Greater than 8.0% but less than 10%

d. Greater than or equal to 10%.

The recommended HbA1c levels are less than or equal to 7.0% for diabetics—a higher target is to be expected for the elderly (65 years and over), pregnant women, and for patients with severe hypoglycaemia.

For the period 1 January to 30 June 2010, 75 services that were part of the HfL program provided valid data on whether HbA1c tests were undertaken for Indigenous clients with Type II diabetes in the last 6 months and 6 of these were urban services, 42 were regional services and 27 were remote services.

- Of the 13,264 Indigenous adults with Type II diabetes who were regular clients of the HfL services, 6,871 (51.8%) had an HbA1c test in the last 6 months. The proportion of Indigenous adults with Type II diabetes who had an HbA1c test in the last 6 months varied by remoteness, from 36% in *Major cities* to 63% in *Very remote* areas (Table 3.05.5).

Table 3.05.5: Number and proportion of Indigenous regular clients[(a)] who are diagnosed with Type II diabetes and HbA1c test in the last 6 months, by remoteness, 1 January–30 June 2010

	Major cities	Inner regional	Outer regional	Remote	Very remote	Total
			Per cent			
Indigenous regular clients with Type II diabetes who had an HbA1c test	36.2	60.6	49.9	52.2	63.0	51.8
Number of Indigenous regular clients with Type II diabetes	2,158	1,474	4,350	2,756	2,526	13,264

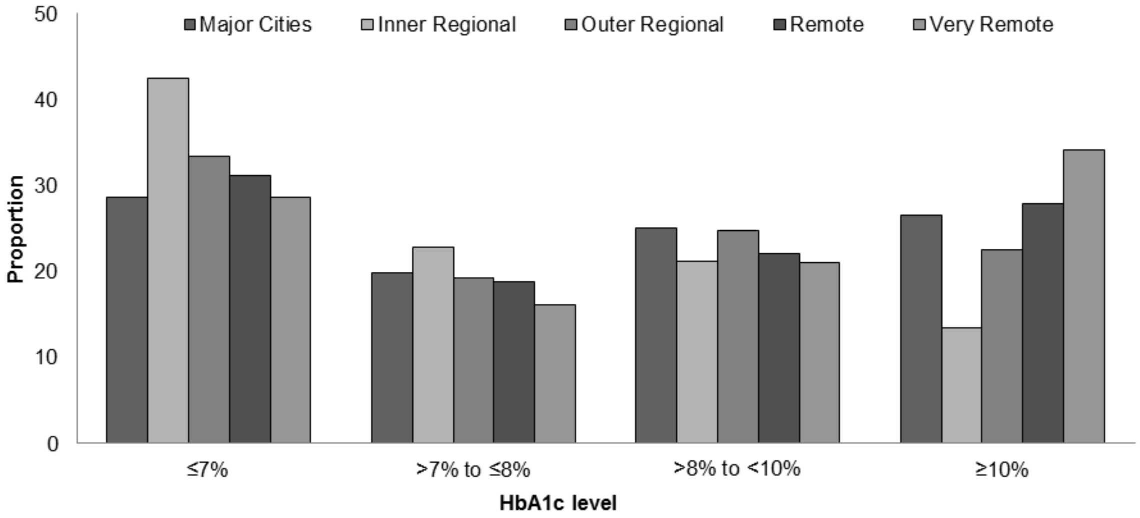
(a) Indigenous regular clients aged 15 years and over.

Notes

1. Valid data for this indicator were provided by 75 services (6 in major cities of Australia, 16 in inner regional Australia, 26 in outer regional Australia, 13 in remote Australia and 14 in very remote Australia).
2. Services used their own definition of regular client.

Source: AIHW, Healthy for Life data collection.

- Of the 6,619 Indigenous adults with Type II diabetes who were regular clients of the HfL services and had an HbA1c test in the last 6 months (and for whom information was available on their HbA1c result), 32% had an HbA1c result less than or equal to 7%, and 26% had a result greater than or equal to 10% (Figure 3.05.2).
- Clients living in *Very remote* areas had the highest proportion of HbA1c results that were greater than or equal to 10% (34%).



(a) Numerator is the number of Indigenous regular clients with Type II diabetes who had an HbA1c test in the last six months by HbA1c result and Denominator is the total number of Indigenous regular clients with Type II diabetes who had an HbA1c test in the last six months.

(b) Indigenous regular clients aged 15 years and over.

Notes

1. Valid data for this indicator were provided by 73 services (5 in major cities of Australia, 15 in inner regional Australia, 26 in outer regional Australia, 13 in remote Australia and 14 in very remote Australia).
2. Services used their own definition of regular client.

Source: AIHW, Healthy for Life data collection.

Figure 3.05.2: Proportion[(a)] of Indigenous regular clients[(b)] with Type II diabetes who had an HbA1c test in the last 6 months, by HbA1c result and remoteness, 1 January–30 June 2010

For the 6 month reporting period ending June 2010, 72 HfL services reported information on the average HbA1c result of clients with Type II diabetes who had an HbA1c test in the last 6 months. These data are presented in Table 3.05.6 below.

- Of the 6,543 Indigenous regular clients of HfL services with Type II diabetes who had an HbA1c test in the last 6 months whose last HbA1c result was recorded, the average HbA1c result was 8.6%.
- The average HbA1c result was highest in *Very remote* areas (9%) and lowest in *Inner regional* areas (7.8%).

Table 3.05.6: Average HbA1c result for Indigenous regular clients[(a)] diagnosed with Type II diabetes who had an HbA1c test in the last 6 months, by remoteness 1 January–30 June 2010

	Major cities	Inner regional	Outer regional	Remote	Very remote	Total
Average HbA1c result (%)	8.8	7.8	8.4	8.8	9.0	8.6
Number of Indigenous regular clients with Type II diabetes who had an HbA1c test in the last six months	782	811	2,155	1,435	1,360	6,543

(a) Indigenous regular clients aged 15 years and over.

Notes

1. Valid data for this indicator were provided by 72 services (6 in major cities of Australia, 15 in inner regional Australia, 25 in outer regional Australia, 13 in remote Australia and 13 in very remote Australia).
2. Services used their own definition of regular client.

Type II diabetes clients—blood pressure tests

Blood pressure is elevated in many people with Type II diabetes. Increased blood pressure levels have been associated with a spectrum of health problems occurring later in people with diabetes—notably cardiovascular disease (especially stroke), eye damage and kidney damage.

The target blood pressure for people with Type II diabetes is less than or equal to 130/80 mmHg (NHMRC 2004).

For the period 1 January to 30 June 2010, 75 services that were part of the HfL program provided data on whether blood pressure tests were undertaken for Indigenous clients with Type II diabetes in the last 6 months.

- Of the 13,264 Indigenous adults with Type II diabetes who were regular clients of the HfL services, 8,251 (62%) had a blood pressure test in the last 6 months. In *Very remote* areas, 77% of Indigenous adults with Type II diabetes had a blood pressure test in the last 6 months, compared with 57% in *Outer regional* areas and 52% in *Major cities* (Table 3.05.7).

Table 3.05.7: Number and proportion of Indigenous regular clients(a) with Type II diabetes who had a blood pressure test in the last six months, by remoteness, 1 January–30 June 2010

	Major cities	Inner regional	Outer regional	Remote	Very remote	Total
Indigenous regular clients with Type II diabetes who had a blood pressure test (%)	52.2	71.5	56.6	61.0	76.6	62.2
Number of Indigenous regular clients with Type II diabetes	2,158	1,474	4,350	2,756	2,526	13,264

(a) Indigenous regular clients aged 15 years and over.

Notes

1. Valid data for this indicator were provided by 75 services (6 in major cities of Australia, 16 in inner regional Australia, 26 in outer regional Australia, 13 in remote Australia and 14 in very remote Australia).
2. Services used their own definition of regular client.

Source: AIHW, Healthy for Life data collection.

- Of the 8,253 Indigenous adults with Type II diabetes who were regular clients of the HfL service and had a blood pressure test in the last 6 months, 3,600 (44%) had a blood pressure result less than or equal to 130/80 mmHg.
- The proportion of Indigenous adults with Type II diabetes who had a blood pressure result less than or equal to 130/80 mmHg was highest for clients living in *Remote areas* and lowest in *Major cities* and *Inner regional* areas (both 40%) (Table 3.05.8).

Table 3.05.8: Number and proportion of Indigenous regular clients[(a)] with Type II diabetes who had a blood pressure test in the last six months with a result less than or equal to 130/80mmHg, by remoteness, 1 January–30 June 2010

Major cities		Inner regional		Outer regional		Remote		Very remote		Total	
%	N/D[(b)]	%	N/D[(b)]	%	N/D[(b)]	%	N/D[(b)]	%	N/D[(b)]	%	N/D[(b)]
40.2	453/1,126	40.2	424/1,054	45.4	1,116/2,456	45.7	768/1,681	43.3	839/1,936	43.6	3,600/8,253

(a) Indigenous regular clients aged 15 years and over.

(b) N (numerator) is the number of Indigenous regular clients with Type II diabetes who had a blood pressure test in the last six months with a result less than or equal to 130/80mmHg. D (denominator) is the total number of Indigenous regular clients with Type II diabetes who had a blood pressure test in the last six months.

Notes

1. Valid data for this indicator were provided by 75 services (6 in major cities of Australia, 16 in inner regional Australia, 26 in outer regional Australia, 13 in remote Australia and 14 in very remote Australia).
2. Services used their own definition of regular client.

Coronary heart disease clients—blood pressure tests

A client has high blood pressure if their systolic blood pressure is greater than or equal to 140 mmHg; or their diastolic blood pressure is greater than or equal to 90 mmHg.

For the period 1 January to 30 June 2010, 75 services that were part of the HfL program provided data on whether blood pressure tests were undertaken for Indigenous clients with coronary heart disease in the last 6 months and provided data on blood pressure test results.

- Of the 3,957 Indigenous adults with coronary heart disease who were regular clients of the HfL services, 2,748 (69%) had a blood pressure test in the last 6 months.

- The proportion of coronary heart disease clients who had a blood pressure test in the last 6 months was highest among clients living in *Very remote* areas (82%), followed by *Inner regional* areas (74%), *Remote areas* (70%), *Outer regional* (69%) and *Major cities* (60%) (Table 3.05.9).

Table 3.05.9: Number and proportion of Indigenous regular clients[(a)] with coronary heart disease who had a blood pressure test in the last six months, by remoteness, 1 January–30 June 2010

Major cities		Inner regional		Outer regional		Remote		Very remote		Total	
%	N/D(b)	%	N/D(b)	%	N/D(b)	%	N/D(b)	%	N/D(b)	%	N/D(b)
60.4	546/904	73.5	472/642	69.4	904/1,302	70.1	497/709	82.3	329/400	69.4	2,748/3,957

(a) Indigenous regular clients aged 15 years and over.

(b) N (numerator) is the number of Indigenous regular clients with coronary heart disease who had a blood pressure test in the last six months. D (denominator) is the total number of Indigenous regular clients with coronary heart disease who had a blood pressure test.

Notes

1. Valid data for this indicator were provided by 75 services (6 in major cities of Australia, 16 in inner regional Australia, 26 in outer regional Australia, 13 in remote Australia and 14 in very remote Australia).
2. Services used their own definition of regular client.

Source: AIHW, Healthy for Life data collection.

- Of the 2,748 Indigenous adults with coronary heart disease who were regular clients of the HfL services and had a blood pressure test in the last 6 months, 1,694 (62%) had a blood pressure result less than 140/90 mmHg.
- Proportions varied by remoteness with the highest in *Very remote* areas (67%) and lowest in *Inner regional* areas (58%) (Table 3.05.10).

Table 3.05.10: Number and proportion of Indigenous regular clients[(a)] with coronary heart disease who had a blood pressure test in the last six months with a result less than 140/90mmHg, by remoteness, 1 January–30 June 2010

Major cities		Inner regional		Outer regional		Remote		Very remote		Total	
%	N/D(b)	%	N/D(b)	%	N/D(b)	%	N/D(b)	%	N/D(b)	%	N/D(b)
60.1	328/546	57.8	273/472	60.7	549/904	65.0	323/497	67.2	221/329	61.6	1,694/2,748

(a) Indigenous regular clients aged 15 years and over.

(b) N (numerator) is the number of Indigenous regular clients with coronary heart disease who had a blood pressure test in the last six months with a result less than 140/90mmHg. D (denominator) is the total number of Indigenous regular clients with coronary heart disease who had a blood pressure test in the last six months.

Notes

1. Valid data for this indicator were provided by 75 services (6 in major cities of Australia, 16 in inner regional Australia, 26 in outer regional Australia, 13 in remote Australia and 14 in very remote Australia).
2. Services used their own definition of regular client.

Divisions of General Practice National Performance Indicators data

Information on the management of patients with diabetes is available from the Divisions of General Practice National Performance Indicators.

Specific information on HbA1c and cholesterol results among patients with diabetes is available for 2010–11 and is presented below.

Of the 112 Divisions for whom online reports were available in 2010–11, 110 reported on the chronic disease management domain. All of these 110, (100%) reported data on the most recent HbA1c result in the past 12 months among patients with diabetes on practice reminder systems (PHC RIS 2013). Of these:

- 60% had recorded their Indigenous diabetes patients' most recent HbA1c result. About 22% of Indigenous patients on the practice diabetes register had an HbA1c result of 7.0% or less (Table 3.05.11). When a patient for whom HbA1c was not measured or recorded was excluded, 37% of Indigenous patients on the practice diabetes register had a result of 7.0% or less.
- 68% had recorded their non-Indigenous diabetes patients' most recent HbA1c status in the past 12 months. Approximately 37% of non-Indigenous patients on the practice diabetes register had an HbA1c result of 7.0% or less (Table 3.05.11). When a patient for whom HbA1c was not measured or recorded was excluded, 55% of non-Indigenous patients on the practice diabetes register had a result of 7.0% or less.

Table 3.05.11: Most recent HbA1c in past 12 months among patients on practice diabetes register, by Indigenous status, 2010–11

	Indigenous		Non-Indigenous		Origin missing	
	Number	**Per cent**	**Number**	**Per cent**	**Number**	**Per cent**

Source: Divisions of General Practice National Performance Indicators 2010–11.

Specific information on cholesterol results among patients with diabetes is available for 2007–08 and is presented in Table 3.05.12. More recent data is unavailable due to a simplification of the National Quality and Performance System (NQPS) in 2007–08, which no longer requires Divisions to report information on this measure.

Of the 105 Divisions who reported on the diabetes domain in 2007–08, 48 (46%) reported data on the most recent total cholesterol among patients with diabetes. Of these:

- Fifty-six per cent had cholesterol results recorded for their Indigenous patients. About 22% of Indigenous patients on the practice diabetes register had a cholesterol result of less than 4.0 mmol/L. When a patient for whom cholesterol was not measured or recorded was excluded, 40% of Indigenous patients with diabetes had a cholesterol result of less than 4.0 mmol/L.
- Sixty-five per cent of Divisions had cholesterol results recorded for their non-Indigenous patients. Approximately 16% had a cholesterol result of less than 4.0 mmol/L. When a

patient for whom cholesterol was not measured or recorded was excluded, 25% of non-Indigenous patients with diabetes had a cholesterol result of less than 4.0 mmol/L (Table 3.05.12).

Table 3.05.12: Most recent cholesterol test in past 12 months among patients with diabetes on register, by Indigenous status, 2007–08

	Indigenous	Non-Indigenous	Origin missing
		Per cent

Data quality issues

Medicare database

MBS items

The MBS items included in this measure have been introduced over the last few years with the child health check item commencing in May 2006. The take-up of new MBS items is influenced by the speed at which practitioners and the population become aware of the new items and how to use them. Also take-up can be influenced by administrative processes and the time taken to change computer systems to incorporate these new items.

Standard Indigenous status question

In November 2002, the ABS standard question on Indigenous identification was included on Medicare enrolment forms. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Under-identification

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete. . There were around 339,310 people who had identified as Aboriginal and/or Torres Strait Islander in this database at May 2012; around 59% of the estimated Aboriginal and Torres Strait Islander population (AHMAC 2012). There has been a rapid expansion in the number of enrolees who identified as Aboriginal and/or Torres Strait Islander, from 47,200 people in August 2004.

Readers should note the following caveats to the Medicare voluntary Indigenous Identifier (VII) adjustment methodology:

- Estimates generated by the adjustment methodology for a given period will vary according to the point in time at which they are calculated, as the adjustment factors will be updated regularly to account for the ongoing change in the population coverage of the VII sample.
- There are inherent uncertainties in the current ABS Indigenous population estimates, and they are therefore described by the ABS as ‘experimental estimates and projections’. The ABS Indigenous population estimates after 2006–07 are experimental projections, based on a number of assumptions about future levels of fertility, mortality and migration. The projections are not predictions or forecasts, but are illustrations of the growth and change in population that would occur if these assumptions were to prevail over the projection period. There can be no certainty that any particular outcome will be realised, or that future outcomes will necessarily fall within the projected ranges.
- The propensity to identify as Aboriginal and/or Torres Strait Islander varies according to the motivations of the individual and the perceived uses of the data in question. For example, it is possible that there are some Aboriginal and Torres Strait Islander people who are registered with the VII but who do not identify as Indigenous for the purposes of the Census, or vice versa.
- In some areas, particularly remote and very remote areas, there is a portion of the Indigenous population that does not ever use the Medicare system. It is therefore possible that the adjustment methodology could overestimate Medicare use by the Indigenous population.

- As the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could be biases in the data that are not addressed by the adjustment methodology.

OATSIH Service Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012).

Healthy for Life data

For the July 2009 to June 2010 reporting period, 79 services submitted data as part of the Healthy for Life (HfL) Program.

Services started submitting their data through an electronic interface (OSCAR) for the February 2008 reporting period. This has improved the quality of data submitted.

Not all of the services were able to provide data for all of the essential indicators and service profile questions included in the HfL data collection. The number of services that were able to provide data varies across the qualitative and quantitative indicators.

There has been an upward trend in the proportion of services that reported on each of the indicators over time, particularly compared with the first reporting period ending June 2007. All of the services reporting provided data for all of the EIs in the period ending December 2009. This proportion decreased slightly in the current reporting period ending June 2010. This may be because services need to report against fewer EIs and do not need to provide most qualitative data in periods ending in December, unlike in annual reporting periods ending in June. The current period had higher proportions of services that reported against most EIs than the previous annual collection period ending June 2009.

In general, the data quality improved noticeably between the period ending June 2008 and the period ending June 2009. The overall level of data quality remained similar in the current period, though there was a different pattern of data quality issues.

The current period ending June 2010 had a different distribution of data quality issues than the previous period. No services had inconsistencies between related indicators, however the number of services with missing data and data out of the expected range increased. The latter might be due to more stringent data checking procedures employed by the AIHW during the current period.

Divisions of General Practice National Performance Indicators

Divisions of General Practice report on a set of National Performance Indicators (NPIs) as part of their accountability to their funding source. Data are submitted to DoHA (through the Primary Health Care Research & Information Service) and are reported annually in the Divisions Performance Indicator Reports.

The NPIs are part of the National Quality Performance System (NQPS). The NQPS is an integral aspect of the Government's primary health policy framework.

The Department has entered into new agreements with the Divisions Network which involve a simplification of the complex NQPS implemented for the 2005–08 contract period. From July 2008 to June 2012 Divisions have reported on a new set of National Performance Indicators (NPIs). For more information go to: (http://www.phcris.org.au/divisions/reporting/div/list.php).

List of tables

List of figures

3.06 Access to hospital procedures

The key hospital procedure differentials between Aboriginal and Torres Strait Islander people and other Australians as measured through standardised rates, ratios and rate differences in hospital separations with the same principal diagnosis

Data sources

Data for this measure come from the AIHW's National Hospital Morbidity Database.

The National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in

data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).

- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

Analyses

Age-standardised rates and ratios have been used for this indicator as a measure of hospitalisations in the Indigenous population relative to other Australians. Ratios of this type illustrate differences between the rates of hospital admissions among Indigenous people and those of other Australians, taking into account differences in age distributions.

Hospitalisations with a procedure recorded

Table 3.06.1 presents the proportion of hospitalisations with a procedure recorded in public hospitals between July 2008 and June 2010 by a number of demographic variables. This table includes all jurisdictions and because the proportions are of those in hospital, and not population rates and, as such, data are not affected by Indigenous under-identification issues as are other data on hospital admissions.

- Between July 2008 and June 2010, excluding hospitalisations for care involving dialysis, there were around 11.5 million hospitalisations with a procedure reported in Australia, 1.7% (191,222) of which were hospitalisations recorded for Indigenous patients.
- Although Indigenous Australians were more likely to be hospitalised than non-Indigenous Australians, they were less likely to undergo a procedure once admitted to hospital. Between July 2008 and June 2010, excluding hospitalisations for care involving dialysis, 60% of Indigenous hospitalisations had a procedure recorded, compared with 81% of non-Indigenous hospitalisations (Table 3.06.1).
- The proportion of hospitalisations with a procedure recorded was highest for Indigenous patients aged 55–64 years and 65 years and over (66% and 67%).
- Patients who were hospitalised in *Remote* or *Very remote* areas were less likely to undergo a procedure (50% and 52% of Indigenous patients and 69% and 64% of non-Indigenous patients) compared with those hospitalised in *Major cities* (71% and 83% for Indigenous and non-Indigenous patients, respectively).
- Both Indigenous and non-Indigenous patients hospitalised in private hospitals were much more likely to undergo a procedure (93% and 94%, respectively) than Indigenous and non-Indigenous patients hospitalised in public hospitals (59% and 72%, respectively).
- Indigenous patients hospitalised in Queensland, New South Wales and South Australia were least likely to receive a procedure (56% in Queensland and 60% in New South Wales and South Australia) and Indigenous patients hospitalised in the Australian Capital territory were most likely to receive a procedure (73%).

(continued)

Table 3.06.1 (continued): Number and proportion of hospitalisations with a procedure recorded[(a)], by Indigenous status, Australia, July 2008 to June 2010

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the p< 0.05 level.

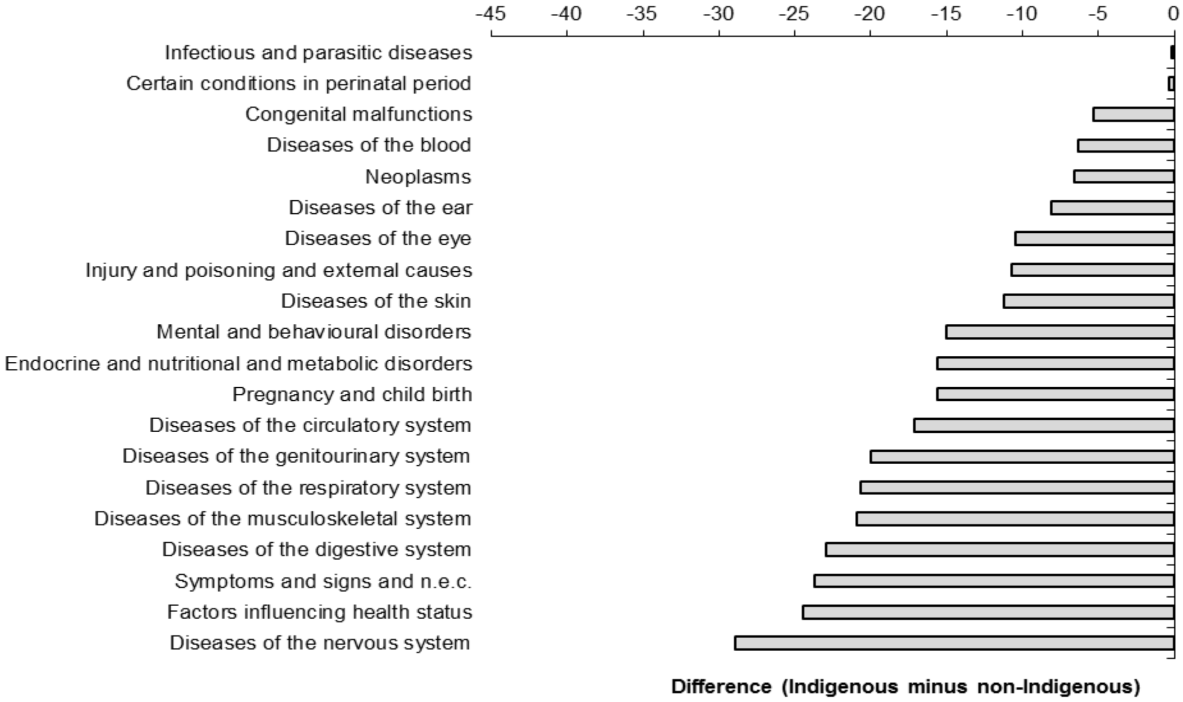
(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.
(b) Ratio—Indigenous divided by non-Indigenous.
(c) Difference—Indigenous minus non-Indigenous.

Notes

1. Proportions are age-standardised using the age-specific rates of non-Indigenous Australians.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
3. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Source: AIHW analysis of National Hospital Morbidity Database.

Figure 3.06.1 and Table 3.06.2 show that between July 2008 and June 2010 in Australia, the proportion of separations with a procedure reported by principal diagnosis was lower for Indigenous patients than for non-Indigenous patients for almost all of the diagnosis chapters (proportions were similar for infectious and parasitic diseases and certain conditions originating in the perinatal period). For example, for 'diseases of the nervous system', 57% of separations for Indigenous patients had a procedure reported, compared with 86% of separations for non-Indigenous patients.



(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.

Notes

1. Proportions are age-standardised using the age-specific rates of non-Indigenous Australians
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
3. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(continued)

Table 3.06.2 (continued): Proportion of separations with a procedure reported[(a)(b)], by principal diagnosis and Indigenous status, Australia, July 2008 to June 2010

(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.

(b) Hospitalisations with a principal diagnosis not stated have been excluded.

(c) Difference—Indigenous minus non-Indigenous.

Notes

1. Proportions are age-standardised using the age-specific rates of non-Indigenous Australians.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
3. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Source: AIHW analysis of National Hospital Morbidity Database.

Remoteness by principal diagnosis.

The diagnostic chapters with the largest gap between Indigenous and non-Indigenous hospitalisations receiving a procedure were fairly consistent across remoteness categories. The same four principal diagnoses ('symptoms, signs, n.e.c.', 'diseases of the nervous system', 'factors influencing health status' and diseases of the musculoskeletal system') were among the top 3 diagnoses with the largest gap in each remoteness category (Table 3.06.3).

Table 3.06.3: Diagnosis chapters with the largest gap between Indigenous and non-Indigenous hospitalisations receiving a procedure[(a)], Australia, 2007–08 to 2009–10[(b)]

Remoteness category	Largest rate difference		Second largest rate difference		Third largest rate difference	
Major cities	Symptoms and signs and n.e.c.	–14.6	Factors influencing health status	–14.4	Diseases of the nervous system	–13.0
Inner regional	Symptoms and signs and n.e.c.	–18.0	Factors influencing health status	–15.8	Endocrine and nutritional and metabolic disorders	–15.7
Outer regional	Diseases of the nervous system	–30.7	Factors influencing health status	–22.5	Diseases of the digestive system	–21.7
Remote	Diseases of the nervous system	–34.4	Diseases of the musculoskeletal system	–29.5	Factors influencing health status	–27.6
Very remote	Factors influencing health status	–30.0	Diseases of the musculoskeletal system	–25.9	Diseases of the nervous system	–25.6

(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.

(b) Data are reported by remoteness of usual residence of the patient hospitalised.

Notes

1. Proportions are age-standardised using the age-specific rates of non-Indigenous Australians.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
3. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Source: AIHW analysis of National Hospital Morbidity Database.

Detailed analysis

A series of more-detailed univariate analysis looked at the association between receiving a procedure once hospitalised and other variables aside from state or territory, remoteness and principal diagnosis, such as age, remoteness by principal diagnosis, sector of hospital, volume of procedures, and impact of principal diagnosis.

Age

Within each age group, the highest proportion of hospitalisations of Indigenous and non-Indigenous patients for which a procedure was reported were for those aged 55–64 and 65–74 years (66% to 67% for Indigenous and 87%and 85% for non-Indigenous patients) (Table 3.06.05). Indigenous patients were less likely to receive a procedure once in hospital than non-Indigenous patients across all age groups. The greatest absolute difference in rates was observed for those aged 35–44 years (rate difference of 26.2 per 100,000) (Table 3.06.4).

Table 3.06.4: Proportion of separations with a procedure reported[(a)], by Indigenous status and age group, Australia, 2008–09 to 2009–10

Age groups (years)	Indigenous	Non-Indigenous
	Per cent	
0–4	44.0	54.3
5–14	59.5	73.1
15–24	53.8	73.1
25–34	54.7	76.5
35–44	54.9	81.1
45–54	59.7	84.5
55–64	65.6	87.0
65+	67.1	85.4
Total age standardised[(b)]	**56.3**	**81.4**

(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.

(b) Total directly age-standardised using the Australian 2001 standard population, calculated using the direct method, age standardised by five year age group to 75+.

Notes

1. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
2. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Source: AIHW analysis of National Hospital Morbidity Database.

Sector

The proportion of separations with a procedure reported was much higher for Indigenous patients admitted to private hospitals than for Indigenous patients admitted to public hospitals (excluding psychiatric hospitals) (76% compared with 59%). The proportion of separations of Indigenous patients with a procedure reported was higher for public psychiatric hospitals than other public hospitals (91% compared with 59%). Indigenous patients admitted to public hospitals, excluding psychiatric hospitals, were less likely to receive a procedure than non-Indigenous patients admitted to public hospitals (ratio of 0.8) (Table 3.06.5).

Of all hospitalisations for Indigenous Australians with a procedure performed, 93.5% were performed in public hospitals (excluding psychiatric hospitals) and 4.6% were performed in public psychiatric hospitals. This compared with 50.3% and 38.9% of hospitalisations for non-Indigenous Australians for these hospital sectors (Table 3.06.6).

Table 3.06.5: Proportion of separations with a procedure reported[(a)], by Indigenous status and sector of hospital, Australia, 2008–09 to 2009–10

Sector	Indigenous	Non-Indigenous
	Per cent	
Public hospital excluding psychiatric	58.8	72.2
Public psychiatric hospital	91.3	92.1
Private hospital	76.2	64.8
Private free standing day hospital facility	99.7	99.5

(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.

Notes

1. Proportions are age-standardised using the age-specific rates of non-Indigenous Australians.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
3. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Number of procedures

Around 25% of all hospitalisations of Indigenous Australians did not have a procedure reported. Around 53% of Indigenous hospitalisations had one procedure reported, 10% had two procedures reported, 6% had three procedures reported and 7% had four or more procedures reported. Indigenous Australians were 1.5 times as likely as non-Indigenous Australians to have no procedures reported and less likely than non-Indigenous Australians to have two or more procedures reported (Table 3.06.7).

Table 3.06.7: Proportion of separations with a procedure reported[(a)], by Indigenous status and number of procedures reported, Australia, 2008–09 to 2009–10

No. of procedures	Indigenous	Non-Indigenous
	Per cent	
0	24.8	16.3
1	52.8	30.2
2	10.0	24.9
3	5.5	14.6
4	2.8	6.1
5–9	3.4	6.9
10+	0.8	1.0

Impact of the individual principal diagnosis

Table 3.06.8 shows the impact of the individual principal diagnosis categories on the likelihood of receiving a procedure in hospital for both Indigenous Australians and non-Indigenous Australians. It shows that, for Indigenous Australians, patients hospitalised for 'diseases of the respiratory system', 'diseases of the nervous system', and 'diseases of the circulatory system' were the least likely to receive a procedure. Two of these chapters—'diseases of the respiratory system' and 'diseases of the digestive system' —were also among the lowest for non-Indigenous Australians.

Table 3.06.8: Impact of principal diagnosis on the likelihood of receiving a procedure in hospital[(a)] (relative to diseases of the skin), by Indigenous status, Australia, 2008–09 to 2009–10

	Indigenous	Non-Indigenous
	Per cent	
Neoplasms	5.97	1.00
Diseases of the blood	5.01	7.97
Endocrine, metabolic & nutritional disorders	0.98	6.80
Diseases of the nervous system	0.86	1.59
Diseases of the eye & adnexa	5.81	2.33
Diseases of the ear & mastoid process	4.61	21.54
Diseases of the circulatory system	0.69	3.79
Diseases of the respiratory system	0.45	0.89
Diseases of the digestive system	1.56	0.75
Diseases of the musculoskeletal system	1.74	2.75
Diseases of the genitourinary system	1.30	3.39
Pregnancy & childbirth	1.20	1.93
Diseases of the skin	1.00	1.25

(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.

Notes

1. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
2. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Multivariate analysis of hospitalisations with a procedure reported

In 2012, the AIHW undertook multivariate regression analyses to examine the relative importance of selected variables, including Indigenous status, in affecting the outcome of whether a patient hospitalised underwent a procedure for the period 2008–09 to 2010–11 in Australia.

In order to test whether distinct differences between Indigenous Australians and other Australians were driving the differences in the likelihood of having a procedure reported, a series of multivariate analyses were run, which included sociodemographic characteristics, state and territory variables, remoteness, hospital sector (public or private), principal diagnosis and total number of additional diagnoses.

After controlling for these other variables, Indigenous status was the 6th most significant variable (if principal diagnosis is counted as a single variable rather than individual variables for each diagnosis) contributing to whether a patient would receive a procedure once in hospital. The odd of receiving a procedure for Indigenous Australians was about 35% less than the odds for other Australians.

The most significant variable contributing to whether a patient would receive a procedure once in hospital was hospital sector. The odds of a person in a private hospital receiving a procedure was five times the odds for a patient in a public hospital.

The second most significant variable was the number of additional diagnoses. Patients hospitalised with additional diagnoses recorded were more likely to receive a procedure than those without additional diagnoses recorded.

Principal diagnosis was the third most significant variable. Of the diagnostic categories, 'neoplasms' was the most significant in increasing the likelihood of receiving a procedure, followed by 'diseases of the digestive system', 'diseases of the musculoskeletal system', 'diseases of the eye and adnexa', 'diseases of the genitourinary system', 'diseases of the blood', 'diseases of the nervous system', 'pregnancy and childbirth', 'diseases of the ear and mastoid process' and 'respiratory diseases'.

The fourth most significant variable was remoteness of usual residence. The odds of receiving a procedure for patients residing in *Remote* and *Very remote* areas were around half as great as the odds for patients residing in *Major cities*.

Age group was the fifth most significant variable, with those aged 55–64 most likely to receive a procedure.

State/territory of usual residence and sex were also significant variables in predicting whether a person would receive a procedure once in hospital, ranking after Indigenous status.

Hospital procedures

Although these exploratory analyses have been critical in identifying some of the factors underlying the disparity between Indigenous and non-Indigenous Australians in the likelihood of receiving a procedure once in hospital, they were not able to fully account for the differences between Indigenous Australians and non-Indigenous Australians. Further research is needed to explore the mechanisms underlying these disparities.

Procedures are clinical interventions that are surgical in nature, carry a procedural risk, carry an anaesthetic risk, require specialised training, and/or require special facilities or equipment that is only available in an acute-care setting. Procedures, therefore, encompass surgical procedures and non-surgical investigative and therapeutic procedures such as X-rays and chemotherapy. Client-support interventions that are neither investigative nor therapeutic (such as anaesthesia) are also included.

- Over the period July 2008 to June 2010, there were 794,477 hospital procedures performed on Indigenous patients in Australia. Approximately one third (34%) of these procedures were for haemodialysis (Table 3.06.9).
- Procedures on the urinary system were the most frequently reported procedures for Indigenous patients (35% of all procedures) followed by haemodialysis procedures. After adjusting for differences in age-structure, Indigenous patients were 5 times more likely to under a urinary system procedure, and 6 times more likely to undergo a haemodialysis procedure than non-Indigenous persons.
- For most other procedure chapters, Indigenous Australians were less likely than non-Indigenous Australians to undergo a procedure. The greatest disparities were for procedures of the nervous system, and procedures of the male genital organs (ratio of 0.3).

.

Time series analyses

Longer term time series data are limited to four jurisdictions that have been assessed as having adequate identification of Indigenous hospitalisations for all years from 1998–99 to 2009–10: Queensland, Western Australia, South Australia and the Northern Territory. These four jurisdictions represent approximately 60% of the Indigenous Australian population.

Additional trend analysis has also been presented for New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined from 2004–05 to 2007–08 for Indigenous and non-Indigenous Australians. New South Wales and Victoria have been assessed as having adequate identification of Indigenous hospitalisations from 2004–05. These six jurisdictions represent approximately 96% of the Indigenous population of Australia.

Note that changes in the level of accuracy of Indigenous identification in hospital records will result in changes in the level of reported hospital procedures for Indigenous Australians. Also, changes in access, hospital policies and practices all have an impact on the level of hospitalisation over time. Caution should be used in interpreting changes over time because it is not possible to ascertain whether a change in reported hospitalisation is due to changes in the accuracy of Indigenous identification or real changes in the rates at which Indigenous people are hospitalised. An increase in procedures may reflect better access to hospitals/hospital procedures rather than a worsening of health

1998–99 to 2009–10

Rates of hospitalisation separations with a procedure, rate ratios and rate differences between Indigenous and non-Indigenous Australians in Queensland, Western Australia, South Australia and the Northern Territory combined over the 11-year period 1998–99 to 2009–10, excluding haemodialysis procedures, are presented in Table 3.06.10 and Figure 3.06.2.

- Over the period 1998–99 to 2009–10 for Queensland, Western Australia, South Australia and Northern Territory combined, there were significant increases in rates of hospitalisation separations with a procedure, excluding dialysis, for both Indigenous and non-Indigenous Australians. The fitted trend implies an average yearly increase in the rate of 5.8 per 1,000 for Indigenous Australians (equivalent to a 32.7% increase over the period) and 4.2 per 1,000 for non-Indigenous Australians (equivalent to a 23.1% increase over the period).
- There was a significant increase in the hospitalisation rate ratios and rate differences between Indigenous and non-Indigenous Australians over the period.

Figure 3.06.2: Rates of hospitalisation separations with a procedure, rate ratios and rate differences between Indigenous and non-Indigenous, Qld, WA, SA and NT, 1998–99 to 2009–10

2004–05 to 2009–10

Rates of hospitalisation separations with a procedure, rate ratios and rate differences between Indigenous and other Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined over the time period 2004–05 to 2009–10, excluding haemodialysis procedures, are presented in Table 3.06.11 and Figure 3.06.3.

- Over the period 2004–05 to 2009–10, for New South Wales, Victoria, Queensland, Western Australia, South Australia and Northern Territory combined, there were significant increases in rates of hospitalisation separations with a procedure, excluding dialysis, for both Indigenous and non-Indigenous Australians. The fitted trend implies an average yearly increase in the rate of 11.0 per 1,000 for Indigenous Australians (equivalent to a 28.3% increase over the period) and 4.9 per 1,000 for non-Indigenous Australians (equivalent to a 10.7% increase over the period).
- There was a significant increase in the hospitalisation rate ratios, and a significant decline in the hospitalisation rate differences, between Indigenous and non-Indigenous Australians over the period.

Females	–33.3	–29.9	–21.4	–14.0	–10.3	–8.0	5.5*	–82.7*
Persons	–35.5	–30.3	–26.7	–15.8	–11.5	–6.4	6.1*	–85.7*

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 2004–05 to 2009–10.

(a) Hospitalisations with a principal diagnosis of care involving dialysis (Z49) have been excluded.

(b) Data are reported by state/territory of usual residence of the patient hospitalised.
(c) Average annual change in rates, rate ratios and rate differences were determined using linear regression analysis.
(d) Per cent change between 2004–05 and 2009–10 based on the average annual change over the period.
(e) Hospitalisation rates for Indigenous Australians divided by hospitalisation rates for non-Indigenous Australians.
(f) Hospitalisation rates for Indigenous Australians minus hospitalisation rates for non-Indigenous Australians.

Notes

1. Rates have been directly age-standardised using the Australian 2001 standard population.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
3. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Figure 3.06.3: Rates of hospitalisation separations with a procedure, rate ratios and rate differences between Indigenous and non-Indigenous, NSW, Vic, Qld, WA, SA & NT, 2004–05 to 2009–10

Coronary heart disease hospital procedures

The AIHW report *Aboriginal and Torres Strait Islander people with coronary heart disease: further perspectives on health status and treatment* (AIHW 2006) looked at the disparities between Aboriginal and Torres Strait Islander people and other Australians with respect to their health status and treatment of coronary heart disease, including the use of coronary procedures in hospital. These data have been updated and the key findings from these analyses are outlined below.

- In 2008–10, among those Australians hospitalised with coronary heart disease, Indigenous Australians were less likely to receive coronary procedures such as coronary angiography and revascularisation procedures than non-Indigenous Australians. This was evident across all age groups (Table 3.06.12). The detailed age-specific rates indicate that, in both relative and absolute terms, the largest differences for both angiography and revascularisation occurred in the 45–54, 55–64 and 65+ year age groups, where the rates for non-Indigenous Australians were around double that for Indigenous Australians and the rate difference was over 17 percentage points for angiography and over 9 percentage points for revascularisation. Revascularisation procedures include percutaneous coronary intervention (PCI) and coronary artery by-pass grafts (CABG).
- After taking the different population age structures into account, the angiography and revascularisation rate for Aboriginal and Torres Strait Islanders was 60% lower than the rate for non-Indigenous Australians (rate ratio of 0.6 for both).
- Similar results were observed when PCI and CABG were analysed separately, with Indigenous Australians generally less likely to receive these procedures than non-Indigenous Australians across all age groups for those hospitalised for coronary heart disease, except for CABG and those in the 35–44 age group (Table 3.05.13). The age-adjusted procedure rate for PCI is around 50% lower than non-Indigenous Australians, although the age-adjusted rate for CABG is 10% lower (age-standardised rate ratio of 0.5 and 0.9, respectively).
- Indigenous Australians with coronary heart disease tended to have more complex cases (measured by the number of comorbidities). In 2008–10, Indigenous people with coronary heart disease were less likely to undergo a coronary procedure across all levels of complexity. In the lower complex group (none, 1 or 2 comorbidities present), Indigenous Australians were no more than half as likely to have a coronary procedure.
- The complexity of cases did not explain the lower procedure rate in Indigenous Australians compared with non-Indigenous Australians.

Table 3.06.12: Use of coronary procedures for those hospitalised with coronary heart disease[(a)], by Indigenous status, Australia, July 2008 to June 2010

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the p < 0.05 level.

(a) Only includes hospitalisations with a principal diagnosis of I20 to I25.

(b) Per cent refers to the proportion of hospitalisations with coronary heart disease as the principal diagnosis receiving either coronary angiography or coronary revascularisation.

(c) Per cent for Indigenous Australians divided by per cent for non-Indigenous Australians.

(d) Per cent for Indigenous Australians minus per cent for non-Indigenous Australians.

(e) Includes those aged less than 25 years.

(f) ASR refers to age-standardised rate using ‘non-Indigenous Australians’ population as the standard population.

Notes

1. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
2. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Digestive system hospital procedures

A study looking at hospital procedures performed for diseases of the digestive tract between July 2003 to June 2006 showed that Aboriginal and Torres Islander people were significantly less likely to receive a corresponding procedure during hospital admissions for complicated or uncomplicated hernias, diseases of the extrahepatic biliary tree and non-neoplastic diseases of the anus or rectum. Indigenous people were as likely as other Australians to receive an appendicectomy for a principal diagnosis recorded as appendicitis, and only marginally less likely to receive a large intestinal resection for admissions where a malignant neoplasm of the large intestine/rectum was recorded as the principal diagnosis. These results were statistically adjusted for age, sex, hospital, urgency of admission, remoteness of usual residence, remoteness of hospital and several comorbidities (Moore et al. 2008).

This study was replicated using the most recent data from July 2008 to June 2010, and results are summarised in Table 3.06.14. The data suggest a similar pattern as the study using data for an earlier period, that being that Aboriginal and Torres Islander people were significantly less likely to receive a corresponding procedure during hospital admissions for complicated or uncomplicated hernias and diseases of the extrahepatic biliary tree, and as likely as non-Indigenous Australians to receive a corresponding procedure for appendicitis; malignant neoplasm of the large intestine/rectum; and non-neoplastic anorectal disease.

Table 3.06.14: Relative odds of receiving corresponding procedure for Indigenous versus non-Indigenous for hospital admissions involving diagnoses of the digestive tract, Australia, June 2008 to July 2010

Principal diagnoses	(Adjusted odds ratio)	95% confidence interval	p value
Appendicitis	0.89	0.80 – 1.00	0.0566 not significant
Complicated and uncomplicated hernias	0.79	0.69 – 0.90	0.0006
Diseases of extrahepatic biliary tree	0.81	0.75 – 0.88	<.0001
Non-neoplastic anorectal disease	0.98	0.87– 1.10	0.7189 not significant
Malignant neoplasm of the large intestine/rectum	1.07	0.86 – 1.31	0.5426 Not significant

Notes

1. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
2. Excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

Cancer research work

A study of 815 Indigenous and 810 non-Indigenous patients diagnosed with cancer in Queensland between 1997 and 2002 found that, after adjustment for stage at diagnosis, treatment and comorbidities, non-Indigenous Australians had better survival than Indigenous patients (hazard ratio = 1.3, 95% CI 1.1–1.5). Indigenous patients were less likely to have had treatment for cancer (surgery, chemotherapy or radiotherapy) and waited longer for surgery (hazard ratio = 0.84, 95% CI 0.72–0.97) than non-Indigenous patients (Valery et al. 2006).

A study in Western Australian of patients who had a cancer registration in the state between 1982 and 2001 found that Indigenous people were less likely to receive surgery for lung cancer and prostate cancer, but not breast cancer (Hall et al. 2004).

Sub-acute care

Sub-acute care service provision in Australia is measured in the National Healthcare Agreement, for which a report is produced annually by the COAG Reform Council (CRC). The most recent report (CRC 2012) presented sub-acute services disaggregated by state, Indigenous status and age group.

Table 3.06.15 presents hospital separation rates involving non-acute care for all states and territories for the financial year 2009–10. Table 3.06.16 presents this information further disaggregated by the type of care provided.

- Nationally, the rate on non-acute care separations for Indigenous Australians was 10.6 per 1,000 compared with 7.8 per 1,000.
- Rates of non-acute care separations were higher for Indigenous Australians than other Australians in most states and territories.
- The highest rate of separations involving non-acute care for Indigenous people was observed in the Australian Capital Territory, at 33.2 separations per 1,000 population. The lowest rate was observed in Tasmania, at 3.0 separations per 1,000 population. For

non-Indigenous people, the rate varied from 5.1 in Tasmania and Northern Territory to 9.0 separations per 1,000 population in Victoria. Rates for the Australian Capital Territory and Tasmania should be interpreted with caution until further assessment of Indigenous identification is completed.

Table 3.06.15: Non-acute care separations[a], by state/territory and Indigenous status, 2009–10[a][b][c]

	NSW	Vic	Qld	WA	SA	Tas[e]	ACT[d][e]	NT	Australia
					Number per 1,000 population				
Indigenous	7.1	12.1	13.5	12.2	7.3	3.0	33.2	11.7	10.6
Other Australians	7.6	9.0	7.1	7.6	6.9	5.1	19.2	5.1	7.8

(a) Rates are age standardised to the Australian population as at 30 June 2001.

(b) Caution should be used in the interpretation of these data as there is some variation in the use of care type categories between jurisdictions.

(c) Cells have been suppressed to protect confidentiality where the presentation could identify a patient or service provider or where rates are likely to be highly volatile, for example, where the denominator is very small. See the Data Quality Statement for further details.

(d) The ACT rates of services should be interpreted with caution since ACT services include a relatively large number of services provided to interstate resident patients while the denominator used in deriving the rates is for ACT population only.

(e) Data for Tasmania and ACT should be interpreted with caution until further assessment of Indigenous identification is completed. The Australian totals for Indigenous/Other Australians do not include data for the ACT, Tasmania and NT (private hospitals only). 'Other Australians' includes separations for non-Indigenous people and those for whom Indigenous status was not stated.

Source: CRC 2012.

- The most common form of non-acute care provided in the 2009–10 financial year was rehabilitation. Rates of separations for care involving rehabilitation for Indigenous people varied from 1.7 per 1,000 in Tasmania to 17.5 per 1,000 in the Australian Capital Territory. The range was somewhat lower for non-Indigenous people, ranging from 0.8 per 1,000 in the Northern Territory to 10.1 per 1,000 in the Australian Capital Territory. The number per thousand nationally was 2.6 per 1,000 for Indigenous people and 1.8 per 1,000 for non-Indigenous Australians.
- Separations involving maintenance care for Indigenous people were most common in the Australian Capital Territory (9.5 per 1,000), while Victoria experienced the lowest rate (0.5 per 1,000) (Table 3.06.16).

Table 3.06.16: Non-acute care separations[(a)], by care type, Indigenous status, sex and state/territory 2009–10[(a)(b)(c)]

	NSW	Vic	Qld	WA	SA	Tas[(e)]	ACT[(d)(e)]	NT	Australia
					Number per 1,000 population

Psychogeriatric care									
Indigenous	0.2	n.p.	n.p.	0.1	n.p.	—	—	n.p.	—
Other Australians	0.3	0.1	0.7	0.1	—	n.p.	0.1	n.p.	0.1
Maintenance care									
Indigenous	1.2	0.5	4.9	3.4	1.5	n.p.	9.5	6.7	1.5
Other Australians	0.9	0.1	1.4	0.7	1.4	0.8	4.9	1.6	0.3

(a) Rates are age standardised to the Australian population as at 30 June 2001.

(b) Caution should be used in the interpretation of these data as there is some variation in the use of care type categories between jurisdictions.

(c) Cells have been suppressed to protect confidentiality where the presentation could identify a patient or service provider or where rates are likely to be highly volatile, for example, where the denominator is very small. See the Data Quality Statement for further details.

(d) The ACT rates of services should be interpreted with caution since ACT services include a relatively large number of services provided to interstate resident patients while the denominator used in deriving the rates is for ACT population only.

(e) Data for Tasmania and ACT should be interpreted with caution until further assessment of Indigenous identification is completed. The Australian totals for Indigenous/Other Australians do not include data for the ACT, Tasmania and NT (private hospitals only). 'Other Australians' includes separations for non-Indigenous people and those for whom Indigenous status was not stated.

Source: CRC 2012.

Table 3.06.17 presents separation rates for Indigenous and non-Indigenous people aged 65 years or over who received sub-acute services. Rates in this table are not age-standardised, and caution should be exercised making Indigenous/non-Indigenous comparisons.

- Separations involving sub-acute services per 1,000 population among those aged over 65 years were lowest in the Northern Territory for both Indigenous people (9.9) and other Australians (36). The highest rates were observed in Victoria for Indigenous people (59), and in New South Wales for non-Indigenous people (78).

Table 3.06.17: Separations for persons aged 65 years or over, receiving sub-acute services[(a)], by Indigenous status and state/territory, 2009–10

	NSW	Vic	Qld	WA	SA	Tas[(a)]	ACT[(a)(b)]	NT	Australia[(b)]
					Number per 1,000 population[(c)]				
Indigenous	30.4	71.9	47.4	33.3	26.7	15.4	202.5	12.3	36.3
Other Australians	101.3	64.6	63.2	46.8	75.0	26.0	127.7	24.8	76.4

(a) Data for Tasmania and ACT should be interpreted with caution until further assessment of Indigenous identification is completed. The Australian totals for Indigenous/Other Australians do not include data for the ACT, Tasmania and NT (private hospitals only). 'Other Australians' includes separations for non-Indigenous people and those for whom Indigenous status was not stated.

(b) The ACT rates of services should be interpreted with caution since ACT services include a relatively large number of services provided to interstate resident patients while the denominator used in deriving the rates is for ACT population only.

(c) Age-standardised to the Australian population as at 30 June 2001.

Emergency department waiting times

Emergency department waiting times are measured as a percentage of patients who are seen within the clinically recommended triage times as advised by the Australasian College of Emergency Medicine. The percentages of patients seen within recommended times are presented in Table 3.06.18.

- Nationally, the percentages of patients seen within the recommended waiting times were similar for Indigenous and other Australians (66 and 69%).
- Rates of Indigenous people seen within the recommended times were higher when compared with other Australians in Victoria, Queensland, Western Australia and the Northern Territory. In all other jurisdictions, rates were similar.
- Rates were similar in the Northern Territory for both Indigenous and non-Indigenous people (52%). The highest rates were observed in Victoria for Indigenous (72%) and in New South Wales for non-Indigenous people (74%).

Table 3.05.18: Patients treated within national benchmarks for emergency department waiting times, by Indigenous status and state/territory, 2010–11[(a)(b)(c)(d)]

	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	Australia
					Per cent				
Indigenous	71	72	71	62	69	57	56	52	66
Other Australians	74	70	66	59	71	59	58	52	69

(a) Data represent the proportion of presentations for which the waiting time to service delivery was within the time specified in the definition of the triage category.

(b) It should be noted that the data presented here are not necessarily representative of the hospitals not included in the NNAPEDCD. Peer group A and B hospitals provided approximately 69 per cent of Emergency Department services.

(c) The quality of the identification of Indigenous patients in National Non-admitted Patient Emergency Department Care Database has not been assessed. Identification of Indigenous patients is not considered to be complete, and completeness may vary among the states and territories.

(d) Excludes records for which the waiting time to service was invalid, and records for which the episode end status was either 'Did not wait to be attended by a health care professional' or 'Dead on arrival, not treated in emergency department'.

Source: CRC 2012.

Elective surgery waiting times

The median and 90th percentile waiting times for elective surgery procedures in public acute care hospitals are presented in Table 3.06.19. Elective surgery refers to a situation where surgery can safely be delayed for 24 hours. The median represents the number of days it took for 50% of patients on the waiting list to be removed from the list, and the 90th percentile represents the time it took for 90% of patients to be removed from the list.

- Nationally in 2010–11, the median waiting time for Indigenous people was 39 days, compared with 36 days for other Australians. In the Northern Territory, the median waiting time for Indigenous people was 42 days, compared with 30 days for other Australians. In South Australia, Indigenous people were on the waiting list for a median of 33 days, and other Australians 38 days.
- The longest 90th percentile waiting time was in the Tasmania for Indigenous people, at 360 days. The 90th percentile for other Australians in the Tasmania was 358 days. The shortest 90th percentile waiting times for both Indigenous and other Australians were observed in Queensland, at 155 and 148 days.
- South Australia was the only jurisdiction where Indigenous people waited less time than other Australians for elective surgery. This difference was observed at both the median (33 and 38 days) and the 90th percentile (157 and 209 days).

Table 3.06.19: Waiting times for elective surgery in public hospitals, by Indigenous status, procedure and state/territory, 2010–11 (days)[(a)]

	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	Australia[(b)]
					Indigenous				
50th percentile	50	34	33	32	33	40	67	42	39
90th percentile	337	209	155	189	157	360	366	276	265
					Other Australians				
50th percentile	47	36	28	29	38	38	77	30	36
90th percentile	333	182	148	158	209	358	378	204	252

(a) Total includes all removals for elective surgery procedures, including but not limited to the procedures listed above.

Source: CRC 2012.

Overnight separations

Age-standardised separation rates where the length of stay in hospital was at least one night are presented in Table 3.06.20. The CRC (2012) has noted that comparability across the jurisdictions for this indicator is not particularly meaningful, but this indicator does depict the level of activity in public and private hospitals as an end point in the health system.

- The highest rates of Indigenous people with overnight stays in hospital were observed in Western and South Australia (364 separations per 1,000 population for both). The lowest rate was observed in Tasmania, at 117 separations per 1,000.
- Tasmania had the lowest rate of overnight stays for other Australians, at 134 separations per 1,000.
- Nationally, the overnight separation rate for Indigenous Australians about twice the rate of other Australians (157 and 288 per 1,000). The greatest difference was in the Western Australia, where the overnight separation rate for Indigenous Australians was over three times that for other Australians (364 compared with 154 per 1,000 population).

Table 3.06.20: Overnight separations, by Indigenous status and state/territory, 2009–10

	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	Australia[(a)]
					Number per 1,000 population[(a)]				
Indigenous	241.9	204.0	278.2	364.0	363.6	116.8	300.2	359.2	288.4
Other Australians	52.8	156.5	160.2	154.1	171.2	133.6	173.1	157.0	156.6

(a) Rates are age standardised to the Australian population as at 30 June 2001.

Data quality issues

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The

proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

3.07 Selected potentially preventable hospital admissions

The number of hospital admissions for potentially preventable conditions for Aboriginal and Torres Strait Islander people expressed as a rate by age group, age–standardised rate and ratio

Data sources

Data for this measure come from the Australian Institute of Health and Welfare's (AIHWs) National Hospital Morbidity Database.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

Analyses

Age-standardised rates and ratios have been used for this indicator as a measure of hospitalisations in the Indigenous population relative to other Australians. Ratios of this type illustrate differences between the rates of hospital admissions among Indigenous people and those of other Australians, taking into account differences in age distributions.

Hospitalisations

- For the two-year period from July 2008 to June 2010, for New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, there were 87,750 potentially preventable hospital admissions of Indigenous people (representing 137 admissions per 1,000 population), compared with 1,226,315 admissions of non-Indigenous people (29 per 1,000 population) (Table 3.07.2).
- In the two year period July 2008 to June 2010, rates for potentially preventable hospital admissions (or potentially preventable conditions) were nearly five times as high for Indigenous Australians compared with non-Indigenous Australians (Tables 3.07.2).

Hospitalisations by age and sex

- In the two-year period from July 2008 to June 2010, Indigenous males and females had higher hospitalisation rates than non-Indigenous males and females for potentially preventable conditions across all age groups (Table 3.07.1).
- Differences in rates between Indigenous and other Australians were particularly marked in the older age groups. For males, the greatest relative difference in rates occurred in the 45–54 year age group where Indigenous males were hospitalised for potentially preventable conditions at 9 times the rate of non-Indigenous males. For females, the greatest relative difference in rates occurred in the 45–54 and 55–64 year age group, where Indigenous females were hospitalised at 10 to 12 times the rate of non-Indigenous females in both these age groups. The age-group with the greatest absolute difference in hospitalisation rates was 65 years and over for males (351 per 1,000) and 55–64 for females (324 per 1,000).
- For Indigenous males and females, hospitalisation rates increased with age from age 15–24 years onwards; for other Australians the rates increased from the age-group 25–34 years onwards. The highest rates were observed among persons aged 65 years and over in both population groups.
- Approximately 46%of Indigenous Australians hospitalised for potentially preventable conditions were males (40,011) and 54% were females (47,739) (Table 3.0.2).

Table 3.07.1: Age-specific hospitalisation rates for potentially preventable conditions (per 1,000 population), by Indigenous status and sex, NSW, Vic, Qld, WA, SA and NT combined, July 2008 to June 2010[a][b][c][d]

(a) Data are from public and most private hospitals, excluding private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Categories are based on the ICD-10-AM sixth edition (National Centre for Classification in Health 2010): codes J10, J11, J13, J14, J153, J154, J157, J159, J168, J181, J188, A35, A36, A37, A80, B05, B06, B161, B169, B180, B181, B26, G000, M014, J45, J46, I50, I110, J81, E10–E14.9, J20, J41, J42, J43, J44, J47, I20, I240, I248, I249, D501, D508, D509, I00–I09, I10, I119, E40, E41, E42, E43, E550, E643, A099, E86, K522, K528, K529, N390, N10, N12, N11, N136, K250, K251, K252, K254, K255, K256, K260, K261, K262, K264, K265, K266, K270, K271, K272, K274, K275, K276, K280, K281, K282, K284, K285, K286, L03, L04, L08, L980, L88, L983, N70, N73, N74, H66, H67, J02, J03, J06, J312, K02, K03, K04, K05, K06, K08, K098, K099, K12, K13, K350, O15, G40, G41, R56, R02. Note some of these codes are for principal diagnosis only, some are for principal or additional diagnosis, and some are principal diagnosis with the exclusion of some procedure codes. For more information on coding used, refer to the AIHW National Healthcare Agreement, PI-22 Selected potentially preventable hospitalisations, 2012.

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised and are for New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland only. These six jurisdictions are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(e) Directly age-standardised using the Australian 2001 standard population.

(f) Rate ratio Indigenous: non-Indigenous Australians.

(g) Rate difference Indigenous minus non-Indigenous Australians.

Notes

1. Population estimates based on the 2006 Census.
2. Care types 7.3, 9 and 10 (newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by state/territory

Table 3.07.2 presents the number of potentially preventable hospital admissions for the two-year period from July 2008 to June 2010 in New South Wales, Victoria, Queensland, Western Australia, South Australia, Tasmania, the Australian Capital Territory and the Northern Territory.

- Over the period from July 2008 to June 2010, Indigenous Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined were hospitalised for potentially preventable conditions at around five times the rate of non-Indigenous Australians.
- In Victoria and the Australian Capital Territory, Indigenous Australians were hospitalised for potentially preventable conditions at around twice the rate of non-Indigenous Australians. In New South Wales, Indigenous hospitalisation rates were around three times as high, and in Queensland, South Australia and the Northern Territory Indigenous hospitalisation rates were around four times as high as for non-Indigenous Australians.
- In Western Australia, Indigenous Australians were hospitalised at 13 times the rate of non-Indigenous Australians. Western Australia also had the greatest absolute difference in hospitalisation rates for potentially preventable conditions. The much higher rates recorded in Western Australia is likely to be a reflection of recent change in coding which has led to substantial increase in the number of hospitalisations for diabetes recorded as an additional diagnosis and consequently the number of potentially preventable hospitalisations (see footnote h in table 3.07.2 below).

Table 3.07.2: Hospitalisations for potentially preventable hospital admissions, by Indigenous status and sex, NSW, Vic, Qld, WA, SA and NT, and Tas and ACT, July 2008 to June 2010[(a)(b)(c)(d)]

* Represents results with statistically significant differences in the Indigenous/other comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Categories are based on the ICD-10-AM sixth edition (National Centre for Classification in Health 2010): codes J10, J11, J13, J14, J153, J154, J157, J159, J168, J181, J188, A35, A36, A37, A80, B05, B06, B161, B169, B180, B181, B26, G000, M014, J45, J46, I50, I110, J81, E10–E14.9, J20, J41, J42, J43, J44, J47, I20, I240, I248, I249, D501, D508, D509, I00–I09, I10, I119, E40, E41, E42, E43, E550, E643, A099, E86, K522, K528, K529, N390, N10, N12, N11, N136, K250, K251, K252, K254, K255, K256, K260, K261, K262, K264, K265, K266, K270, K271, K272, K274, K275, K276, K280, K281, K282, K284, K285, K286, L03, L04, L08, L980, L88, L983, N70, N73, N74, H66, H67, J02, J03, J06, J312, K02, K03, K04, K05, K06, K08, K098, K099, K12, K13, K350, O15, G40, G41, R56, R02. Note some of these codes are for principal diagnosis only, some are for principal or additional diagnosis, and some are principal diagnosis with the exclusion of some procedure codes. For more information on coding used, refer to the AIHW National Healthcare Agreement, PI-22 Selected potentially preventable hospitalisations, 2012.

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised and are for New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland only. These six jurisdictions are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(e) Directly age-standardised using the Australian 2001 standard population in five-year age groups to 75+ for NSW, Vic, Qld, WA, SA and NT. Directly age-standardised using the Australian 2001 standard population in five-year age groups to 65+ for Tasmania and the ACT.

(f) Rate ratio—Indigenous: other.

(g) Rate difference Indigenous minus non-Indigenous Australians.

(h) The much higher rates recorded in Western Australia is likely to be a reflection of a coding rule which was recently introduced in Western Australia whereby all patients hospitalised with a principal diagnosis of ‘care involving dialysis’ who were clinically documented as having diabetes must now have diabetes recorded as an additional diagnosis (ABS & AIHW 2008).

(i) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

Notes

1. Population estimates based on the 2006 Census.
2. Care types 7.3, 9 and 10 (newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by remoteness

Hospitalisation rates for potentially preventable hospital conditions in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory are presented by Australian Standard Geographical Classification (ASGC) in Table 3.07.3, covering the period July 2008 to June 2010.

- Indigenous Australians in all remoteness areas were more likely to be hospitalised for potentially preventable conditions than non-Indigenous Australians. The difference in rates between Indigenous and non-Indigenous Australians was statistically significant for all ASGC areas.
- Rates of hospitalisations per 1,000 head of population were highest for Indigenous people living in *Remote* areas, at 324 per 1,000. The rate was highest for non-Indigenous Australians who lived in *Very remote* areas, at 36 per 1,000. The lowest rates were observed in *Inner regional* areas for Indigenous people (116 per 1,000) and *Major cities* for non-Indigenous Australians (27 per 1,000).
- Indigenous people were hospitalised for these conditions at a rate of 10 times that of non-Indigenous Australians in *Remote* areas of Australia. In *Inner regional* areas, where the lowest ratio was observed, Indigenous Australians were hospitalised at a rate of around four times that of non-Indigenous Australians.

Table 3.07.3: Hospitalisations for potentially preventable conditions by Indigenous status and remoteness, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010[a][b][c][d][e][f]

(a) Data are from public and most private hospitals, excluding private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory

(b) Categories are based on the ICD-10-AM sixth edition (National Centre for Classification in Health 2010): codes J10, J11, J13, J14, J153, J154, J157, J159, J168, J181, J188, A35, A36, A37, A80, B05, B06, B161, B169, B180, B181, B26, G000, M014, J45, J46, I50, I110, J81, E10–E14.9, J20, J41, J42, J43, J44, J47, I20, I240, I248, I249, D501, D508, D509, I00–I09, I10, I119, E40, E41, E42, E43, E550, E643, A099, E86, K522, K528, K529, N390, N10, N12, N11, N136, K250, K251, K252, K254, K255, K256, K260, K261, K262, K264, K265, K266, K270, K271, K272, K274, K275, K276, K280, K281, K282, K284, K285, K286, L03, L04, L08, L980, L88, L983, N70, N73, N74, H66, H67, J02, J03, J06, J312, K02, K03, K04, K05, K06, K08, K098, K099, K12, K13, K350, O15, G40, G41, R56, R02. Note some of these codes are for principal diagnosis only, some are for principal or additional diagnosis, and some are principal diagnosis with the exclusion of some procedure codes. For more information on coding used, refer to the AIHW National Healthcare Agreement, PI-22 Selected potentially preventable hospitalisations, 2012.

(c) Financial year reporting.

(d) Data are reported by state/territory and remoteness of usual residence of the patient hospitalised.

(e) Directly age-standardised using the Australian 2001 standard population, by 5 year age groups to 65+

(f) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(g) LCL = lower confidence limit.

(h) UCL = upper confidence limit.

(i) Rate ratio Indigenous: non-Indigenous.

(j) Rate difference Indigenous- non-Indigenous.

(k) Includes remote Victoria.

(l) Excludes remote Victoria.

(m) Total includes hospitalisations where ASGC is missing.

Notes

1. Rates are calculated using the remoteness distribution by Indigenous status, age and sex based on the 2006 ERP and applied to the 2008–10 population projections (Series B) based on the 2006 Census.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Hospitalisations by diagnosis

Table 3.07.4 presents data on the top 10 potentially preventable hospital admissions for Aboriginal and Torres Strait Islander people in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined for the two-year period July 2008 to June 2010.

- During this period, diabetes complications were the most common type of potentially preventable condition among Indigenous Australians in the six jurisdictions, followed by chronic obstructive pulmonary disease (COPD) and convulsions and epilepsy. Indigenous Australians were hospitalised at around twelve times the rate of non-Indigenous Australians for diabetes complications, and around five times the rate for convulsions and epilepsy and COPD.

- Pyelonephritis (kidney infection) was the fourth most common potentially preventable condition for which Indigenous Australians were hospitalised, at almost 3 times the rate of non-Indigenous Australians.
- For most potentially preventable conditions, the average length of stay in hospital was higher among non-Indigenous Australians (4 days) compared with Indigenous Australians (3 days).
- COPD and congestive heart failure were responsible for the greatest average number of days in hospital for both Indigenous and non-Indigenous Australians. Indigenous Australians stayed an average of 5 and 6 days in hospital for these conditions respectively, compared with around 7 days for both conditions for non-Indigenous Australians.

Table 3.07.4 (continued): Top 10 potentially preventable hospital admissions, by Indigenous status, NSW, Vic, Qld, WA, SA and NT combined, July 2008 to June 2010[(a)(b)(c)(d)]

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals, excluding private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Categories are based on the ICD-10-AM sixth edition (National Centre for Classification in Health 2010): codes J10, J11, J13, J14, J153, J154, J157, J159, J168, J181, J188, A35, A36, A37, A80, B05, B06, B161, B169, B180, B181, B26, G000, M014, J45, J46, I50, I110, J81, E10–E14.9, J20, J41, J42, J43, J44, J47, I20, I240, I248, I249, D501, D508, D509, I00–I09, I10, I119, E40, E41, E42, E43, E550, E643, A099, E86, K522, K528, K529, N390, N10, N12, N11, N136, K250, K251, K252, K254, K255, K256, K260, K261, K262, K264, K265, K266, K270, K271, K272, K274, K275, K276, K280, K281, K282, K284, K285, K286, L03, L04, L08, L980, L88, L983, N70, N73, N74, H66, H67, J02, J03, J06, J312, K02, K03, K04, K05, K06, K08, K098, K099, K12, K13, K350, O15, G40, G41, R56, R02. Note some of these codes are for principal diagnosis only, some are for principal or additional diagnosis, and some are principal diagnosis with the exclusion of some procedure codes. For more information on coding used, refer to the AIHW National Healthcare Agreement, PI-22 Selected potentially preventable hospitalisations, 2012.

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised and are for New South Wales, Victoria, Queensland, Western Australia, South Australia, and the Northern Territory only. These six jurisdictions are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(e) Directly age-standardised using the Australian 2001 standard population.

(f) LCL = lower confidence limit.

(g) UCL = upper confidence limit.

(h) Rate ratio—Indigenous: non-Indigenous.

(i) Rate difference—Indigenous minus non-Indigenous.

(j) All potentially preventable hospital admissions. Note that the sum of the number of hospitalisations for each condition may exceed the total because more than one potentially preventable condition can be diagnosed for each hospital separation.

Notes

1. Rates for Indigenous are calculated using population estimates based on the 2006 Census (SERIES B).
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by diagnosis and age group

Table 3.07.5 presents data on the top three potentially preventable hospital admissions by age group for Aboriginal and Torres Strait Islander people in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined for the two-year period from July 2008 to June 2010.

- During this period, ear, nose and throat infections were the most common type of potentially preventable condition among Indigenous Australians aged less than one year of age, followed by dehydration and gastroenteritis. Indigenous infants were hospitalised at almost three times the rate of non-Indigenous infants for ear, nose and throat infections, and at around three and a half times the rates for dehydration and gastroenteritis.
- Dental conditions were the most common reason for hospitalisation among Indigenous Australians aged 1–14 years of age. This group was hospitalised at almost two times the rate of non-Indigenous Australians at this age. Dental conditions accounted for 7% of total hospitalisations of Indigenous Australians in this age group.
- Convulsions and epilepsy was the most common reason for hospitalisation among Aboriginal and Torres Strait Islander people aged 15–24 years, followed by pyelonephritis. Indigenous Australians of this age were hospitalised at just over three times the rate of non-Indigenous Australians for convulsions and epilepsy, and at twice the rates of non-Indigenous Australians for pyelonephritis. These two conditions each accounted for approximately 1% of total hospitalisations of Indigenous Australians aged 15–24 years.
- Complications associated with diabetes was the most common reason for potentially preventable hospitalisation among Indigenous Australians aged 25–44, 45–64 and 65 years and older. Indigenous Australians were hospitalised at between 8 and 22 times the rate of non-Indigenous Australians for diabetes complications in these age groups. Diabetes complications were responsible for 5%, 10% and 15% of total hospitalisations of Indigenous Australians in these age groups, respectively.
- COPD was another common type of potentially preventable condition responsible for hospitalisation among Indigenous Australians aged 45–64 and 65 years and over. Indigenous Australians were hospitalised at eight times the rate of non-Indigenous Australians for this condition in the 45–64 year age group, and at three and a half times the rate in the 65 year and over age group. COPD accounted for 1% and 3% of total hospitalisations of Indigenous Australians aged 45–64 and 65 years and over, respectively.

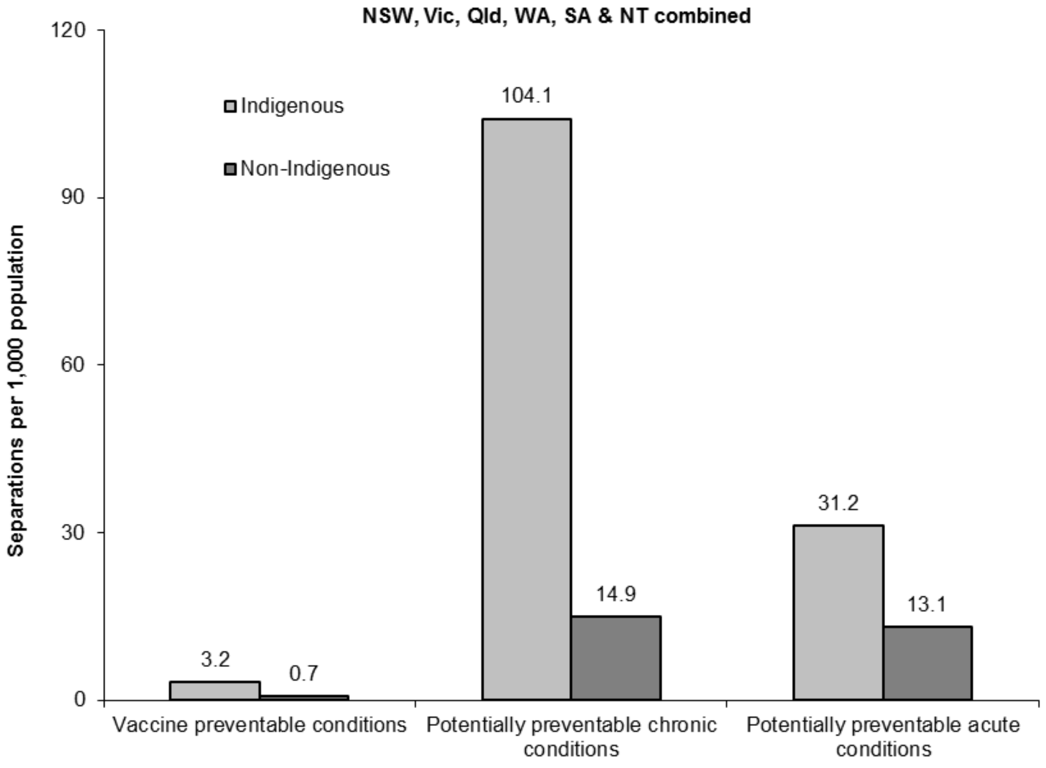
Comparison of vaccine preventable, chronic and acute conditions

- For the two-year period from July 2008 to June 2010, in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, Indigenous Australians had higher hospitalisation rates for vaccine preventable conditions, potentially preventable chronic conditions and potentially preventable acute conditions (Figure 3.07.1).
- For potentially preventable chronic conditions, hospitalisation rates for Indigenous Australians were 7 times the rate of hospitalisations for non-Indigenous Australians.



Source: AIHW analysis of National Hospital Morbidity Database.

Figure 3.07.1: Age-standardised hospitalisation rates for potentially preventable hospital admissions, by Indigenous status and sex, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010

Time series analysis

In this section we present hospitalisation rates, rate ratios and rate differences between Indigenous and other Australians for vaccine-preventable conditions over the period 1998–99 to 2009–10. Due to changes in coding since 2007–08, resulting in an apparent decline for diabetes complication and increase for gastroenteritis, time series data are not currently available for hospitalisation rates for chronic and acute conditions under this performance measure.

Vaccine-preventable conditions from 1998–99 to 2009–10

Hospitalisation rates, rate ratios and rate differences between Indigenous and other Australians for vaccine-preventable conditions, such as influenza, pneumonia, diphtheria, measles, mumps and rubella, over the period 1998–99 to 2009–10 are presented in Table 3.07.6 and Figure 3.07.2.

- In Queensland, Western Australia, South Australia and the Northern Territory combined, there were statistically significant declines in hospitalisation rates for vaccine-preventable conditions among Indigenous Australians during the period 1998–99 to 2009–10. The fitted trend implies an average yearly decline in the rate of around 0.7 per 1,000 for Indigenous Australians, which was equivalent to a 40% decline in the rate over the period.
- Over the same period, there were statistically significant declines in hospitalisation rates for non-Indigenous Australians. The fitted trend implies an average yearly decline in the rate of around 0.1 per 1,000 for other Australians, which is equivalent to a 42% decline in the rate over the period.
- Most of the declines in rates for vaccine-preventable hospitalisations over this period were attributable to a sharp decline in hospitalisation rates from 1998–99 to 1999–00. This is likely to be the result of the introduction of a number of vaccination programs and changes to the Australian Standard Vaccination Schedule in 1999 and 2000. Such changes include: funding for influenza and pneumococcal vaccine for Indigenous adults aged 50 years and over and for those aged 15–49 years who are at high risk from these diseases; funding of influenza vaccine for non-Indigenous Australians aged 65 years and over; inclusion of diphtheria-tetanus-pertussis—hepatitis B vaccine on the childhood immunisation schedule; and the new requirement for full immunisation against hepatitis B and haemophilus influenza type B (Hib) at 12 months of age (Menzies et al. 2004).
- There was no significant change in the hospitalisation rate ratio between Indigenous and non-Indigenous Australians for vaccine-preventable conditions over the period 1998–99 to 2009–10. There was a significant decline in the hospitalisation rate difference between Indigenous and non-Indigenous Australians for vaccine-preventable conditions over the period 1998–99 to 2009–10 (40%).

Figure 3.07.2: Hospitalisation rates, rate ratios and rate differences between Indigenous and other Australians for vaccine preventable conditions, Qld, WA, SA and NT combined, 1998–1999 to 2009–2010

Vaccine-preventable conditions from 2004–05 to 2009–10

Hospitalisation rates, rate ratios and rate differences between Indigenous and non-Indigenous Australians over the period 1998–99 to 2009–10 for New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined are presented in Table 3.07.7 and Figure 3.07.3.

- In New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, there were no significant changes in hospitalisation rates for vaccine-preventable conditions among Indigenous Australians during the period 2004–05 to 2009–10. Over the same period, there were also no significant changes in hospitalisation rates for non-Indigenous Australians.
- There was no significant change in the hospitalisation rate ratio between Indigenous and non-Indigenous Australians for vaccine-preventable conditions over the period 2004–05 to 2009–10. There was a significant increase in the hospitalisation rate difference between Indigenous and non-Indigenous females for vaccine-preventable conditions over the period 2004–05 to 2009–10 (43%).

* Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 2004–05 to 2009–10.

(a) Data are reported by state/territory of usual residence of the patient hospitalised. Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Average annual change in rates, rate ratios and rate differences determined using linear regression analysis.

(c) Per cent change between 2004–05 and 2009–10 based on the average annual change over the period.

(d) Hospitalisation rates for Indigenous Australians divided by the hospitalisation rates for non-Indigenous Australians.

(e) Hospitalisation rates for Indigenous Australians minus the hospitalisation rates for non-Indigenous Australians.

Notes

1. Rates have been directly age-standardised using the 2001 Australian standard population.
2. Population estimates are based on 2006 census.
3. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Data quality issues

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments. For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections. Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and ACT data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions. From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only. In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

3.08 Cultural competency

Available measures on aspects of cultural competency including discrimination and barriers to accessing services for Indigenous Australians

Data sources

Data for this measure come from the 2008 National Aboriginal and Torres Strait Islander Social Survey, the 2004–05 National Aboriginal and Torres Strait Islander Health Survey, the Australian Institute of Health and Welfare (AIHW) National Hospital Morbidity Database, the 2006 Census of Population and Housing, the Australian Government Department of Education, Employment and Workplace Relations (DEEWR) Higher Education Student Statistics Collection, the National Centre for Vocational Education Research (NCVER) National Vocational Education and Training (VET) Provider Collection and the OATSIH Services Reporting (OSR) data collection.

National Aboriginal and Torres Strait Islander Social Survey 2008

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

National Aboriginal and Torres Strait Islander Health Survey 2004–05

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

Census of Population and Housing

The Census of Population and Housing is conducted by the ABS at 5-yearly intervals, and is designed to include all Australian households. The Census uses the ABS standard Indigenous status question for each household member.

The 2011 Census is the most recent, however data for the Indigenous population was not yet released at the time of writing this report. Therefore data included in this report come from the 2006 Census. In 2006, the ABS enhanced the sample for the Post-Enumeration Survey to include remote areas. The measured undercount for Indigenous Australians was 11.5%.

DEEWR Higher Education Statistics Collection

The Australian Government Department of Education, Employment and Workplace Relations (DEEWR) is the responsible agency for the Higher Education Statistics Collection, which includes information from higher education institutions such as universities and colleges of advanced education. This data collection contains statistics relating to students enrolled in higher education courses between 1 January and 31 December of each year in each Australian higher education provider.

Although universities design and produce their own enrolment forms, DEEWR has provided institutions with suggested wording for questions relating to Indigenous status (ABS 2003). Approximately 3% of students in this data collection have a 'not stated' Indigenous status. At the moment these are recorded as non-Indigenous, although plans are under way to record the 'not stated' responses separately.

National Vocational Education and Training (VET) Provider Collection

The National Centre for Vocational Education Research is Australia's main provider of vocational education and training (VET) sector research and statistics. VET is a national system designed to give workers the skills for particular occupations and industries. The VET sector includes providers that receive public VET funding, such as technical and further education organisations, higher education institutions, other government providers (for example, agricultural colleges), community education providers, government-funded private registered training organisations, schools funded through government allocations for VET, and all other Commonwealth and state recurrent and specific-purpose funded VET, regardless of the location of the training organisation.

OATSIH Services Reporting data collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in

earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Data Analyses

Discrimination experienced by Indigenous people

The 2008 NATSISS collected information about feelings of discrimination experienced by Indigenous people when contacting service providers and in other situations. In total, 27% of Indigenous people 27% of Indigenous Australians aged 15 years and over felt that they had been discriminated in the 12 months preceding the survey (Table 3.08.1).

- Indigenous people were most likely to report feelings of discrimination when in contact with 'members of the public' and when in contact with 'police, security people and lawyers or while in a court of law' (both 11%) (Table 3.08.1).
- Apart from other situations (0.4%), feelings of discrimination were least likely to be reported by Indigenous people while participating in sporting, recreational or leisure activities (3.0%) and while at school, university, a training course or another educational setting (4.0%).
- The Australian Capital Territory had the highest proportion of Indigenous Australians who had experienced discrimination in the last 12 months (36%), followed by Western Australia (34%) and South Australia (32%). Tasmania had the lowest (9%) (Table 3.08.2).
- Of those who experienced discrimination, 15% said that they felt discriminated against by doctors, nurses or other hospital staff, and 1.5% said that they avoided situations with such staff (Table 3.08.3).
- Indigenous people in remote areas were slightly less likely to experience discrimination in the previous 12 months (26%) than those in non-remote areas (28%). However, they were slightly more likely to report being discriminated against by doctors, nurses or other hospital staff (17% of those in remote areas who reported discrimination compared with 14% in non-remote areas) (Table 3.08.3).
- Similar proportions of Indigenous males and females said that they had experienced discrimination in the previous 12 months (28% and 27% respectively), however a higher proportion of females felt discriminated against by doctors, nurses or other hospital staff (18% of females who had experienced discrimination, compared with 11% of males) (Table 3.08.4).

Table 3.08.1: Situations or places felt discriminated against, Indigenous persons aged 15 years and over, 2008

Situations or places felt discriminated against	No	Per cent
Applying for work or when at work	26,351	8.1
At home, by neighbours or at someone else's home	16,351	5.0
At school, university, training course or other educational setting	12,061	3.7

Cultural barriers to accessing services

Measurement of the accessibility of health services involves factors other than the distance people must travel and the financial costs incurred (Ivers et al. 1997). Many Indigenous persons or communities do not have adequate access to either culturally appropriate services or to other suitable arrangements and, where culturally appropriate services exist, they are often under-resourced or unable to meet community needs (Bell et al. 2000). The perception of cultural barriers may cause Indigenous people to travel substantial distances in order to access health services delivered in a more appropriate manner than those available locally (Ivers et al. 1997). The willingness of Indigenous people to access health services may be affected by such factors as community control of the service, the gender of health service staff and the availability of Aboriginal and Torres Strait Islander staff, particularly where the patient's proficiency in spoken and written English is limited (Ivers et al. 1997). Some Indigenous people do not feel comfortable attending services such as a private general practice because of educational, cultural, linguistic and lifestyle factors, and will do so only when there is no alternative or their health problem has worsened (Bell et al. 2000). Information on language and other cultural barriers comes from the 2008 NATSISS.

Cultural barriers to accessing health services by remoteness

- The 2008 NATSISS showed that 26% of Indigenous Australians aged 15 years and over had problems accessing health services. (Table 3.08.5).
- Of Indigenous Australians aged 15 years and over who had problems accessing health services, 7% thought that the health services were not culturally appropriate.
- A higher proportion of Indigenous Australians aged 15 years and over in remote areas had problems accessing health services than those in non-remote areas (36% compared with 23%).

Cultural barriers to accessing services by state/territory

- The 2008 NATSISS showed that 30% of Indigenous Australians aged 15 years and over had problems accessing service providers (Table 3.08.6).
- Around 5% of Indigenous persons surveyed said that services were not culturally appropriate (includes people who were treated badly or discriminated against and who do not trust the service), while 30% identified other barriers (such as transport/distance problems, cost of service, no services in the area, waiting time too long or service not available at the required time).
- Victoria had the highest proportion of respondents who said that services were not culturally appropriate (7%), followed by Western Australia and New South Wales (both 6%). The Australian Capital Territory also had a relatively high proportion of respondents who identified this factor as a barrier (7%), however, this estimate has a high relative standard error and should be used with caution.

Cultural barriers to accessing services by remoteness

- Indigenous Australians in remote areas were more likely than those in non-remote areas to have problems accessing service providers (42% compared with 26%, respectively) (Table 3.08.7).
- A slightly higher proportion of Indigenous Australians in non-remote areas than remote areas said that services were not culturally appropriate (9% of those who experienced problems accessing services, compared with 6%, respectively), didn't trust services (12% and 8% respectively), or said that they were treated badly or discriminated against (5% and 3% respectively).
- Indigenous females were more likely than Indigenous males to experience problems accessing service providers (32% compared with 27%, respectively) (Table 3.08.8).
- Similar proportions of males and females identified barriers relating to cultural appropriateness, trust of services and bad treatment or discrimination.

Language

Not being able to speak, read and write English proficiently can mean that some Indigenous Australians find it difficult to approach services such as health and welfare services. They may therefore miss out on important information and entitlements and may have difficulty reading and completing forms (House of Representatives Standing Committee on Aboriginal and Torres Strait Islander Affairs 1993).

- In 2008, about 12% of Indigenous people reported that they spoke a language other than English at home. This figure includes 10.4% who said they spoke an Indigenous language at home and 1.4% who said they spoke another language. Indigenous persons living in remote areas of Australia were much more likely to report speaking an Australian Indigenous language at home (38.8%) than those living in non-remote areas (1.2%) (Figure 3.08.2; Table 3.08.9).

Communicating with service providers

The 2008 NATSISS collected information on whether Indigenous Australians had difficulty communicating with English speakers.

- Approximately 17% of males and females aged 15 years and over who speak an Indigenous language reported that they had difficulty understanding English speakers, being understood by English speakers or both (Table 3.08.10).
- Indigenous persons living in remote areas were more likely to report experiencing difficulty (18%) than those in non-remote areas of Australia (6%) (Table 3.08.10).
- 83% of people in non-remote areas whose main language was an Indigenous language could also speak English. In remote areas, 66% could also speak English.

Table 3.08.10: Difficulty communicating with English speakers, Indigenous persons aged 15 years and over whose main language is Indigenous, by remoteness, 2008

	Non-remote	Remote	Total
		Per cent	
Difficulty understanding English speakers	5.2	6.8	6.7

Treatment of Indigenous Australians seeking health care

- According to the 2004–05 NATSIHS, 16% of Indigenous Australians aged 15 years and over felt that they were treated badly, because of being Aboriginal or Torres Strait Islander, when seeking health care in the previous 12 months (Table 3.08.11).
- This proportion was similar for Indigenous people in remote and non-remote areas.
- Anger was the most common response of those who felt they were treated badly (experienced by 67% of those who were treated badly), with many people also feeling sorry for the perpetrator (31%) or sad (28%) (Table 3.08.11).
- A higher proportion of Indigenous people in remote areas than non-remote areas felt sad when treated badly (35% compared with 25%, respectively), or felt ashamed or worried about it (32% compared with 10%).
- One-third (33%) of Indigenous people who were treated badly said that they try to avoid the person or situation, with similar proportions for Indigenous people in remote and non-remote areas.

Table 3.08.11: Treatment of Indigenous Australians when seeking health care in the last 12 months, by remoteness, 2004–05

Discharge from hospital against medical advice

- Between July 2008 and June 2010, there were 14,053 discharges from hospital of Indigenous people against medical advice in Australia (Table 3.08.12). This represented 2.4% of all hospital separations of Indigenous Australians.
- After adjusting for differences in age-structure, Indigenous persons were 5 times more likely than non-Indigenous Australians to be discharged against medical advice.
- Indigenous people in *Very remote* and *Remote* areas of Australia were most likely to be discharged from hospital against medical advice (3.5% and 3.1% of all hospitalisations respectively). In these areas, Indigenous people were 5 times and 4 times more likely than non-Indigenous people to be discharged against medical advice.

Table 3.08.12: Discharges against advice, by Indigenous status and remoteness, (excluding mental and behavioural disorders), Australia, July 2008 to June 2010[a][b][c][d]

	Number		Per cent		Age-standardised

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in Northern Territory, Australia Capital Territory and Tasmania

(b) Financial year reporting.

(c) Data are reported by state/territory of usual residence of the patient hospitalised.

(d) Proportions are indirectly age-standardised using the age-specific proportions for non-Indigenous Australians as the standard.

(e) Rate ratio is the rate for Indigenous Australians divided by the rate for non-Indigenous/Other Australians.

(f) Rate difference is the rate for Indigenous Australians minus the rate for non-Indigenous/Other Australians.

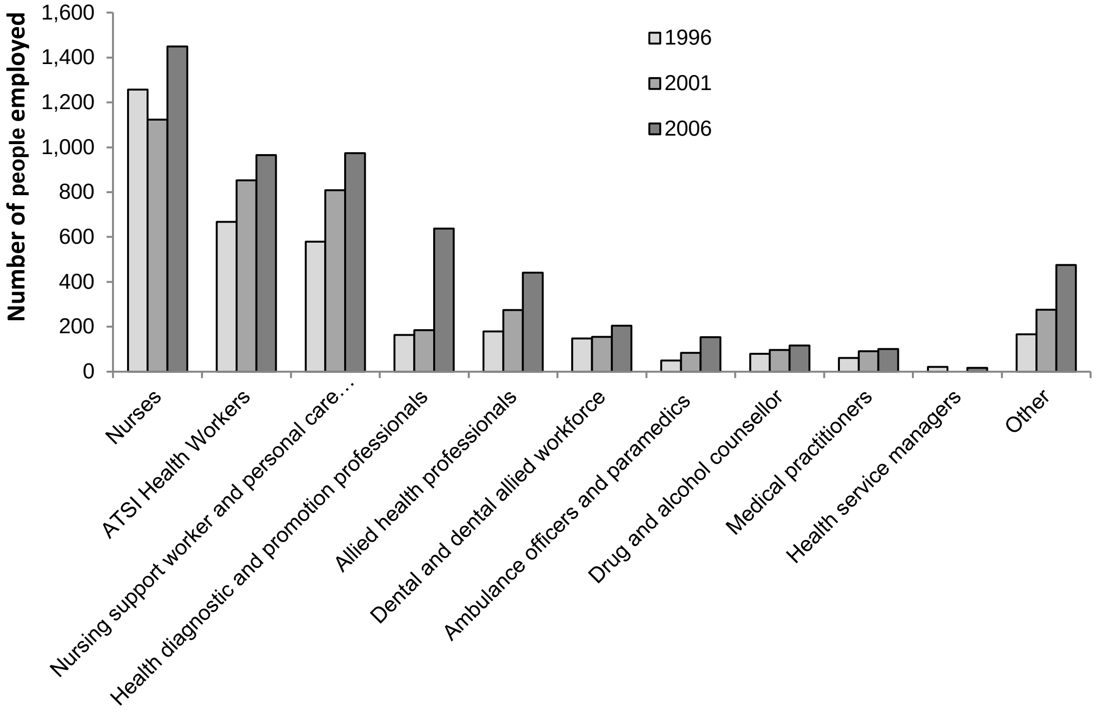
Notes

1. Principal diagnosis of mental & behaviour disorders excluded from analysis.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Indigenous people in health-related occupations

- Between 1996 and 2006 there was an increase in the number of Indigenous people employed in most health-related occupations (Figure 3.08.3 and Table 3.10.1).
- Substantial increases occurred in the areas of health diagnostic and promotional professions (increasing by 289% over the period), and allied health professions (increasing by 146%) (See indicator 3.10, Table 3.10.1).



Source: AIHW analysis of the ABS census data.

Figure 3.08.3: Aboriginal and Torres Strait Islander People employed in selected health-related occupations, 1996, 2001 and 2006

Indigenous students enrolled in health-related courses

Data on Indigenous student enrolments in higher education university health-related courses are available from the DEEWR Higher Education Students Statistics Collection. Data on Indigenous students enrolled in health-related courses in the VET sector are available from NCVER National VET Provider Collection.

- In 2010, there were 1,766 Indigenous students aged 15 years and over enrolled in university health-related courses, and 5,100 Indigenous students enrolled in health-related courses in the VET sector (See indicator 3.20, Tables 3.20.1 and 3.20.10).

Governance of Aboriginal and Torres Strait Island primary health care services

- In 2010–11, 74% of Aboriginal and Torres Strait Islander primary health care services had a board or governance committee where all members were Indigenous. This decreased slightly from 2008–09 where the proportion was 77% (Figure 3.08.4).
- Over the same period, there was a slight increase in the proportion of services with no Indigenous board members, rising from 9% to 14%.
- In 2010–11, there were approximately 5,731 full-time equivalent (FTE) staff employed in Indigenous primary health-care services, 3,875 (68%) health staff and 1,856 (32%) administration and support staff. The majority of both health and administration staff were Indigenous (51% and 57%, respectively) (see Table 3.13.3 in Indicator *3.13 Competent governance* of this report).
- In 2010–11, the most common health promotion/prevention group activity run by Aboriginal and Torres Strait Islander primary health-care services was community based education and prevention groups (71%), followed by living skills groups (e.g. cooking and nutrition groups) and sport/recreation/physical education groups (each 65%) and women's groups (60%) (see Figure 3.03.9 in Indicator *3.03 Health promotion* of this report).
- In 2010–11, around 20% of Indigenous primary health-care services offered bush tucker nutrition programs or traditional healing, 12% provided bush medicine programs and 4% offered other traditional health care programs (see Figure 3.03.8 in Indicator 3.03 *Health promotion* of this report).

Data quality issues

National Aboriginal and Torres Strait Islander Social Survey

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User’s guide (ABS 2010).

National Aboriginal and Torres Strait Islander Health Survey

The NATSIHS uses the standard Indigenous status question. The 2004–05 NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially ‘as reported’ by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through

careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

National Hospital Morbidity Database

The scope of the NHMD is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

Census of Population and Housing

The Census uses the National health data dictionary standard Indigenous status question and it is asked for each household member. Measures that are drawn from Census data are subject to broad data concerns relating to the unexplainable growth in the Aboriginal and Torres Strait Islander population since the 1991 Census, and the limitations of self-identification. Other Census data issues relate to the accuracy of the Census count itself; for example, whether people are counted more than once, or are undercounted (ABS 1996).

Although the Census data are adjusted for undercounts at the person level to arrive at the estimated resident population, no such adjustment is done at the household level. This affects the accuracy of the person counts at the household level to provide adjusted household estimates.

DEEWR Higher Education Schools Statistics Collection

The Higher Education Schools Statistics Collection comprises information on enrolments and award completions from public and private higher education institutions that are required to report to DEEWR.

Institutions receive detailed written documentation about what information is required to be furnished in the form of an electronic help file. Universities design and produce their own statistical information (enrolment) forms. These are designed to be used by institutions to collect the required information from students. DEEWR has provided institutions with suggested wording for questions relating to Indigenous status, language spoken at home and disability (ABS 2009).

Approximately 3% of students in this data collection have a 'not stated' Indigenous status. At the moment these are recorded as non-Indigenous, although plans are under way to record the 'not stated' responses separately.

National Centre for Vocational Education Research data

This collection gathers information from providers (in receipt of public VET funding) about activity of the VET system in Australia. The collection encompasses all delivery funded wholly or in part from public funds.

NCVER maintains a database of information on persons undertaking vocational education and training. Each state and territory collates data from their training providers on a student, course and module/unit of competency basis. These data are compiled into AVETMISS format and validated by each training organisation before being submitted to NCVER. The data are then further validated and quality checked for inconsistencies before being used for the production of statistical reports (ABS 2009).

Non-identification rates for Indigenous students in these data are high. Care also needs to be taken when comparing data across jurisdictions for load pass rates, as average module durations vary across jurisdictions (SCRGSP 2005).

OATSIH Service Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the Aboriginal and Torres Strait Islander Health Services Report, 2010–11 (AIHW 2012).

3.09 Discharge against medical advice

The rate at which Aboriginal and Torres Strait Islander people leave hospital against medical advice or are discharged at their own risk

Data sources

Data for this measure come from the AIHW's National Hospital Morbidity Database.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in

data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).

- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

Analyses

Age-standardised rates and ratios have been used for this indicator as a measure of hospitalisations in the Indigenous population relative to non-Indigenous Australians. Ratios of this type illustrate differences between the rates of hospital admissions among Indigenous people and those of non-Indigenous Australians, taking into account differences in age distributions.

Tables presented below report the crude and age standardised proportions of hospitalisations that involved discharge against medical advice in Australia.

- For the period from July 2006 to June 2008, there were 71,304 hospitalisations in Australia where the patient left hospital against medical advice or was discharged at their own risk, 14,052 (20%) of which were hospitalisations of Indigenous patients.
- For approximately 2% of all hospitalisations of Indigenous Australians, the patient was discharged against medical advice; compared with 0.4% for non-Indigenous Australians.
- After adjusting for differences in age structure, Indigenous persons were almost five times as likely as non-Indigenous persons to discharge themselves from hospital against medical advice.

Hospitalisations by age and sex

- Indigenous Australians aged 25–34 (4.9%) had the highest proportions of discharge from hospital against medical advice (Table 3.09.1).
- Indigenous males were more likely than Indigenous females to discharge against medical advice (2.7% compared with 2.2%) (Table 3.09.2).

Table 3.09.1: Discharges from hospital against medical advice (excluding mental and behavioural disorders), by Indigenous status and age group, Australia, July 2008 to June 2010[(a)(b)(c)]

Hospitalisations by state/territory

Table 3.09.3 presents hospitalisations for which patients were discharged against medical advice for the two-year period from July 2008 to June 2010 for all jurisdictions.

- The Northern Territory had the highest proportion of Indigenous persons hospitalised who discharged against medical advice (3.7%).
- After adjusting for differences in age structure, Indigenous persons were five times as likely as non-Indigenous persons to discharge themselves from hospital against medical advice. Disparities were greatest in South Australia, Western Australia and Victoria where Indigenous persons discharged from hospital against medical advice at seven, six and five times the rate of non-Indigenous persons respectively (Table 3.09.3).

Table 3.09.3: Discharges from hospital against medical advice (excluding mental and behavioural disorders), by Indigenous status and state/territory, July 2008 to June 2010[(a)(b)(c)]

Hospitalisations by remoteness

Hospitalisation rates for discharge against medical advice in Australia are presented by remoteness using the Australian Standard Geographical Classification (ASGC) in Table 3.09.4, covering the period July 2008 to June 2010.

- Discharge against medical advice increased with increasing remoteness, with Indigenous persons living in *Very remote* areas having the highest proportions of hospitalisations involving discharge against medical advice (3.5%). The same pattern was evident for non-Indigenous Australians.
- Indigenous Australians in all remoteness areas were more likely to discharge from hospital against medical advice than non-Indigenous Australians.
- Indigenous people were discharged against advice at a rate 5 times that of non-Indigenous Australians in *Very remote* areas of Australia. In *Major cities*, where the lowest rates of discharge against medical advice were observed, Indigenous Australians were hospitalised at a rate of four times that of non-Indigenous Australians.

Table 3.09.4: Discharges against advice (excluding mental and behavioural disorders), by Indigenous status and remoteness, Australia, July 2008 to June 2010[(a)(b)(c)(d)]

	Number		Per cent of total separations		Age-standardised			
	Indig.	Non-Indig.	Indig.	Non-Indig.	Indig.	Non-Indig.	Ratio[(e)]	Rate difference[(f)]
Major cities	2,355	37,688	1.8	0.4	1.5	0.4	4.0*	1.1*
Inner regional	1,614	11,029	1.9	0.4	1.4	0.4	3.8*	1.0

Very remote	3,927	341	3.5	0.7	3.3	0.7	4.8*	2.6*
Missing	*206*	*912*	*13.5*	*1.7*	*11.4*	*1.7*	*6.7**	*9.7**
Total	**14,052**	**57,252**	**2.4**	**0.4**	**2.0**	**0.4**	**5.1***	**1.6***

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in Northern Territory, Australia Capital Territory and Tasmania.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification in Health 2010).

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised.

(e) Rate ratio is the rate for Indigenous Australians divided by the rate for non-Indigenous Australians.

(f) Rate difference is the rate for Indigenous Australians minus the rate for non-Indigenous Australians.

Notes

1. Principal diagnosis of mental & behaviour disorders excluded from analysis.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by principal diagnosis

- The most common principal diagnoses of hospitalisations of Indigenous Australians who were discharged against medical advice were injury and poisoning (3,125 separations) followed by respiratory diseases (1,874). These two groups of diagnoses represented 36% of all Indigenous hospitalisations discharged against medical advice. As a proportion of all separations for each specific diagnoses group, discharge against medical advice for Indigenous people was also highest for injury and poisoning (6.9%), followed by diseases of the skin (6.8%), symptoms, signs and abnormal clinical and laboratory findings (5.9%) and diseases of the nervous system (5.6%) (Table 3.09.5).
- The greatest relative difference between Indigenous and non-Indigenous Australians in the proportion of hospitalisations involving discharge against medical advice was for hospitalisations with a principal diagnosis of diseases of the musculoskeletal system (14.1 times the proportion of non-Indigenous Australians). This was followed by diseases of the digestive system (11.9 times) and diseases of genitourinary system (9.9 times) (Table 3.09.5).
- In contrast, the greatest absolute difference between Indigenous and non-Indigenous Australians in the proportion of hospitalisations involving discharge against medical advice was for hospitalisation with a principal diagnosis of diseases of the skin (5.1 per 1,000), followed by infectious and parasitic diseases (4.8 per 1,000).

(continued)

Table 3.09.5 (continued): Discharges from hospital against medical advice, by Indigenous status and principal diagnosis (excluding mental and behavioural disorders), Australia, July 2008 to June 2010(a)(b)(c)

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data exclude private hospitals in the Northern Territory, Australia Capital Territory and Tasmania.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification in Health 2010).

(c) Financial year reporting.

(d) Percentage of hospital separations (excluding mental and behavioural disorders) in the period 2008–09 to 2007–10.

(e) Rate ratio is the rate for Indigenous Australians divided by the rate for non-Indigenous Australians.

(f) Rate difference is the rate for Indigenous Australians minus the rate for non-Indigenous Australians.

(g) Includes: neoplasms, certain conditions originating in the perinatal period, diseases of the ear and mastoid process, diseases of the eye and adnexa, diseases of the genitourinary system, diseases of the musculoskeletal system, diseases of the blood and blood-forming organs and certain disorders involving the immune system, and congenital malformations and deformations and chromosomal abnormalities.

(h) Includes hospitalisations for which no principal diagnosis was recorded. Excludes mental and behavioural disorders (F00–F99).

Note: Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by remoteness by principal diagnosis

Analysis of hospitalisation rates for discharge against medical advice by remoteness and principal diagnosis shows that the diagnostic chapters with the highest proportions of Indigenous separations ending in discharge against medical advice varied by region (Table 3.09.6). Diseases of the nervous system had the highest proportions of Indigenous separations involving discharge against medical advice in *Major cities* and regional areas; whilst in *Remote* areas, infectious and parasitic diseases, and in *Very remote* areas, diseases of the skin had the highest proportions.

Table 3.09.6: Diagnosis chapters with the highest proportions of Indigenous separations ending in discharge against medical advice, Australia, July 2008 to June 2010

	Highest		Second highest		Third highest	
Remoteness category	**Chapter**	**Proportion**	**Chapter**	**Proportion**	**Chapter**	**Proportion**
Major city	Diseases of the nervous system	3.2	Symptoms and signs and n.e.c.	3.2	Diseases of the skin	2.9
Inner regional	Diseases of the nervous system	2.7	Diseases of the digestive system	2.6	Injury and poisoning and external causes	2.5
Outer regional	Diseases of the nervous system	4.7	Endocrine and nutritional and metabolic disorders	3.9	Infectious and parasitic diseases	3.8
Remote	Infectious and parasitic diseases	7.2	Endocrine and nutritional and metabolic disorders	6.8	Diseases of the ear	6.8
Very remote	Diseases of the skin	11.4	Diseases of the musculoskeletal system	7.8	Infectious and parasitic diseases	7.4

Notes

1. Exclude principal diagnosis of mental & behavioural disorders ICD–10–AM 'F'; Care types 7.3, 9, 10; and patients treated in Tasmania, the NT or the ACT private hospitals.
2. Proportions are age-standardised using the age-specific proportion of non-Indigenous Australians.

Source: AIHW analysis of National Hospital Morbidity Database.

Average length of stay

- Indigenous patients who were discharged from hospital against medical advice stayed in hospital longer on average than Indigenous patients who were not discharged from hospital against medical advice (3.1 days compared with 2.5 days) (Table 3.09.7).
- Indigenous patients who were discharged from hospital against medical advice had a similar average length of stay to non-Indigenous patients who discharged from hospital against medical advice (3 days).

Table 3.09.7: Average length of stay in hospital for patients discharged against medical advice (excluding diagnoses for mental and behavioural disorders), by Indigenous status and sex, Australia, 2008–09 to 2009–10

	Discharged against medical advice					Not discharged against medical advice

Time series analyses

Time series data are presented for the four jurisdictions that have been assessed as having adequate identification of Indigenous hospitalisations for all years from 1998–99 to 2009–10 in Queensland, Western Australia, South Australia and the Northern Territory. These four jurisdictions represent approximately 60% of the Indigenous Australian population. New South Wales and Victoria were identified as having adequate identification of Indigenous hospitalisations from 2004–05 onwards, and are included as part of a separate time series analysis (2004–05 to 2009–10).

The number and rate per 1000 population of hospitalisations for which Indigenous and non-Indigenous Australians were discharged against medical advice over the period 1998–99 to 2009–10 are presented in Table 3.09.8 and Figure 3.09.1. Data for the period 2004–05 to 2009–10 are presented in Table 3.09.9 and Figure 3.09.2.

- Over the period 1998–99 to 2009–10, in Queensland, Western Australia, South Australia and the Northern Territory combined, there was a significant increase in the rate of Indigenous and non-Indigenous hospitalisations that involved discharge against medical advice (20% for Indigenous and 36% for non-Indigenous). Indigenous Australians were discharged from hospital against medical advice at a rate of 16 per 1,000 in 1998–99 which increased to 20 per 1,000 in 2009–10. Non-Indigenous persons were discharged from hospital against medical advice at a rate of 0.9 per 1,000 in 1998–99 which increased to 1.1 per 1,000 in 2009–10.
- Over the period 2004–05 to 2009–10, in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, there was a significant increase in the rate of Indigenous and non-Indigenous hospitalisations that involved discharge against medical advice (12% for Indigenous and 22% for non-Indigenous).

Note that changes in the level of accuracy of Indigenous identification in hospital records will result in changes in the level of reported hospital separations for Indigenous Australians. Also, changes in access, hospital policies and practices all have an impact on the level of hospitalisation over time. Caution should be used in interpreting changes over time because it is not possible to ascertain whether a change in reported hospitalisation is due to changes in the accuracy of Indigenous identification or real changes in the rates at which

Indigenous Australians are hospitalised. An increase in hospitalisation rates may reflect better access to hospitals, rather than a worsening of health.

Additional information

Multivariate analysis of discharge from hospital against medical advice

In 2012 the AIHW undertook multivariate regression analyses to examine the relative importance of selected variables including Indigenous status, in affecting the outcome of whether a patient discharged themselves from hospital against medical advice for the period 2008–09 to 2009–10 in Australia. All eight states and territories were included in the multivariate analyses. Thus, the analyses sought to answer the question of whether compositional differences between the two populations accounted for differences in the likelihood of discharge against medical advice. Categories of included variables were state and territory, remoteness, and principal diagnoses. All analyses controlled for age and sex.

Results from the multivariate analyses showed that Indigenous status was the most significant variable contributing to whether a patient would discharge themselves from hospital against medical advice, even after controlling for the other factors. Indigenous Australians were three times as likely to discharge from medical advice as other Australians.

Remoteness of hospital location was the second most significant variable affecting the outcome of discharge from hospital against medical advice. Persons hospitalised in outer regional areas were more likely to discharge against medical advice as patients hospitalised in other areas.

Sex was the third most significant variable affecting the outcome of discharge from hospital against medical advice. Females were around 30% less likely to discharge against medical advice as males.

Principal diagnosis was the fourth most significant variable affecting the outcome of discharge from hospital against medical advice. Persons hospitalised with a principal diagnosis of ‘mental and behavioural disorders’ were most likely to discharge against medical advice, followed by ‘symptoms, signs and abnormal findings’, ‘diseases of the nervous system’, and ‘injury and poisoning’.

Age-group was the next most significant variable, followed by state of hospital, remoteness of usual residence and state/territory of usual residence. Results show that where a patient is hospitalised is more important than where a patient resides.

Although these exploratory analyses have been important in identifying some of the factors underlying the disparity between Indigenous and other Australians in the likelihood of discharging against medical advice, they were not able to fully account for the differences. Thus, they point to the need for further research in other domains such as individual factors (such as psychosocial, personal circumstances, health and wellbeing, and cultural issues) and community level factors (such as trust/mistrust in system) and hospital level factors (such as staff, hospital policies and the environment).

Data quality issues

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of Newborn episodes that did not include qualified days, and records for Hospital boarders and Posthumous organ procurement have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The

proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in Major cities to 97% in Remote and Very remote areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021 (ABS 2009).

List of tables

List of figures

3.10 Access to mental health services

Access to mental health care services such as hospitals, community mental health care, doctors and Aboriginal and Torres Strait Islander Primary health-care services by Aboriginal and Torres Strait Islander people

Data sources

Data for this indicator come from Medicare data, the Bettering the Evaluation and Care of Health (BEACH) Survey; OATSIH Services Reporting data collection; National Community Mental Health Care Database; National Hospital Morbidity Database; National Residential Mental Health Care Database; National Health Workforce Data Set; National Aboriginal and Torres Strait Islander Health Survey (NATSIHS); and the Supported Accommodation Assistance Program National Data Collection.

Medicare Database

Medicare enrolment application forms are lodged by persons wishing to enrol with Medicare at Medicare offices in each state/territory or by mail. Information from these forms is entered directly into the Medicare database, which is held by the Department of Health and Ageing (DoHA).

In November 2002, the ABS standard question on Indigenous identification was included on this form. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete.

As at 1 May 2012, 339,310 Indigenous Australians were enrolled on the VII database. This represents 59% of the estimated total Indigenous population (AHMAC 2012).

Medicare data presented in this report have been adjusted for under-identification. There are a number of caveats to the VII adjustment methodology, including that as the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could therefore be biases in the data that are not addressed by the adjustment methodology.

Bettering the Evaluation and Care of Health (BEACH) Survey

Information about encounters in general practice is available from the BEACH survey, which was conducted by the AIHW Australian General Practice Statistics and Classification Centre, in the Family Medicine Research Centre (FMRC) at the University of Sydney until March 2012, when the AIHW ceased its involvement in the BEACH program. The FMRC continues to run BEACH the results are now published by the University of Sydney. The most recent annual reports can be found at http://ses.library.usyd.edu.au/handle/2123/7771.

Information is collected from every changing random sample of approximately 1,000 general practitioners (GPs) from across Australia each year. A sample of 100 consecutive GP–patient encounters is collected by each GP.

The number of Indigenous patients identified in the BEACH survey is likely to be underestimated because some GPs might not ask the question on Indigenous status, or the patient may choose not to identify themselves (AIHW 2002).

Data are presented for the 5-year period 2006–07 to 2010–11, during which there were around 6,000 GP encounters with Aboriginal and Torres Strait Islander patients recorded in the survey, representing 1.2% of total GP encounters.

OATSIH Services Reporting data collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

National Community Mental Health Care Database

Information on the use of community mental health services by Indigenous people is available from the AIHW National Community Mental Health Care Database (NCMHCD). The NCMHCD is a collation of data on specialised mental health services provided to non-admitted patients, in both government-operated community and hospital-based ambulatory care services. For example, community mental health services, outpatient clinics and day clinics.

The quality of the Indigenous identification in this database varies by jurisdiction and should be interpreted with caution. All state and territory health authorities provided information on the quality of the data for the NCMHCD 2009–10. New South Wales, Victoria, Western Australia, Tasmania, and the Australian Capital Territory considered the quality of

Indigenous status data to be acceptable. Queensland reported that the quality of Indigenous status data was acceptable at the broad level, however, there are quality issues regarding the coding of more specific details (that is, Aboriginal, Torres Strait Islander, or Both Aboriginal and Torres Strait Islander). Northern Territory considered the quality to be below the previous year's standard as a result of lack of compliance with non-mandated data collection items by new external (non-mental health) health service provider data entry. South Australia indicated that the quality of these data is uncertain at this stage.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and ACT (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010a):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).

- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

National Residential Mental Health Care Database

Information on the use of residential mental health services by Indigenous people is available from the AIHW National Residential Mental Health Care Database (NRMHCD). The information collected in the database is a nationally agreed set of common data elements collected by service providers and based on the National Minimum Data Set for Residential Mental Health Care.

The quality of Indigenous identification in this database varies by jurisdiction.

As with hospitalisation data, service contacts for which the Indigenous status of the client was not reported have been included with hospitalisations for non-Indigenous people under the 'other' category.

National Health Workforce Data Set

The AIHW, in collaboration with Health Workforce Australia, is the custodian of the National Health Workforce Data Set (NHWDS) that describes these professionals and the work they do.

The NHWDS combines data from the National Registration and Accreditation Scheme (NRAS) with health workforce survey data collected when annual registrations are renewed. The mandatory registration process is administered by the Australian Health Practitioner Regulation Agency (AHPRA) and includes an optional survey that collects additional demographic and workforce information.

All practitioners in these professions must be registered with the AHPRA to practice in Australia, and this applies whether they trained in Australia or overseas. The AHPRA manages the NRAS, which replaced jurisdiction-based registration with a single national registration and accreditation system. As part of this scheme, the AHPRA supports National Health Practitioner Boards, which regulate registered health professions under nationally consistent legislation. Registration for each profession is granted by the relevant boards, subject to applicants meeting the standards and policies set by each.

At its introduction, the NRAS covered registration for 10 health professions, with another four scheduled for inclusion from 1 July 2012 (see below). In all, this represents more than 530,000 registered health professionals.

Since 1 July 2010, these professions have been regulated: chiropractors, dental practitioners (including dentists, dental hygienists, dental prosthetists and dental therapists), medical practitioners, nurses and midwives, optometrists, osteopaths, pharmacists, physiotherapists, podiatrists, and psychologists.

From 1 July 2012, these health professions are included: Aboriginal and Torres Strait Islander health practitioners, Chinese medicine practitioners, medical radiation practitioners, and occupational therapists.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

Supported Accommodation Assistance Program National Data Collection

The Supported Accommodation Assistance Program National Data Collection (SAAP NDC) was collected from 1996 to June 2011. It was designed to capture data on government response to homelessness, and focuses on services provided by agencies funded under the Supported Accommodation Assistance Program which specifically target and provide services to people who are homeless or at risk of homelessness. Therefore, service providers who do not receive government funding and general service providers (that is, which are not 'specialist homelessness agencies') are not included in this data collection.

From July 2011, the SAAP NDC was replaced by the Specialist Homelessness Services Collection (SHSC). The SHSC was developed by the AIHW in collaboration with the Australian Government Department of Families, Housing, Community Services and Indigenous Affairs and relevant departments of all state and territory governments. Key differences between the SAAP NDC and SHSC include the expanded scope of agencies included in the SHSC, to agencies funded under the National Affordable Housing Agreement (NAHA) and National Partnership Agreement on Homelessness (NPAH); the inclusion of children as clients in their own right in SHSC (whereas accompanying children were recorded on their parent's form in SAAP NDC); and the monthly collection of client information and services provided for the SHSC (whereas SAAP NDC information was only collected at the end of a support period).

Analyses

Age-standardised rates and ratios have been used for this indicator as a measure of the Indigenous population relative to other Australians. Ratios of this type illustrate differences between the rates among Indigenous people and those of other Australians, taking into account differences in age distributions.

Medicare data

Claims made as patients for psychologist and psychiatric care

In 2010–11, Indigenous Australians were less likely to have claimed through Medicare as private patients for psychologist care (96 per 1,000 compared with 153 per 1,000) and psychiatric care (46 compared with 88 per 1,000) (Table 3.10.1).

Ambulatory mental health services claimed

In 2009–10, the rate of ambulatory mental health services claimed through Medicare was lower for Indigenous Australians than for non-Indigenous Australians (202 per 1,000 compared with 320 per 1,000) (Table 3.10.2). This includes private services for psychiatric, psychological, GP and other allied health care.

Clinical mental health services

In 2009–10, there were 28,303 Indigenous Australians who received clinical mental health services. After adjusting for differences in age-structure a lower proportion of Indigenous Australians received clinical mental health services than non-Indigenous Australians (5.6% compared with 6.2%) (Table 3.10.3).

Table 3.10.1: MBS services claimed, by Indigenous status, Australia, 2010–11

	Indigenous services	Non-Indigenous services	Indigenous crude rate/ 1,000	Indigenous age-std-rate/ 1,000	Non-Indigenous crude rate/ 1,000	Non-Indigenous age-std-rate/ 1,000	Rate ratio	Rate difference
MBS services claimed								
Psychologist	48,957	3,312,542	87	96	152	153	0.62	–57.61
Psychiatrist	18,498	1,963,608	33	46	90	88	0.52	–42.68

Source: Medicare Financing & Analysis Branch, Department of Health and Ageing.

Table 3.10.2: Rate of ambulatory mental health services provided, by sex, Indigenous status, remoteness and SEIFA, by state/territory, 2009–10(a)

	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	Aust	
	Age standardised rate per 1000 population(b)									No.
Indigenous status(c)										
Indigenous	299.2	394.4	176.5	88.8	192.1	305.7	325.3	31.5	202.5	98,728
Non-Indigenous	315.6	391.9	294.9	256.7	301.5	290.7	242.1	116.2	320.3	6,864,684

(a) Disaggregation by state/territory, remoteness area and SEIFA is based on the patient’s postcode at the date their last service was processed in the reference period. This is not necessarily the location where the service was received.

(b) Rates are age-standardised to the Australian population as at 30 June 2001.

(c) Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. Indigenous rates are therefore modelled and should be interpreted with caution. These statistics are not derived from the total Australian Indigenous population, but from those Aboriginal and Torres Strait Islander people who have voluntarily identified as Indigenous to Medicare Australia. The statistics have been adjusted to reflect demographic characteristics of the overall Indigenous population, but this adjustment may not address all the differences in the service use patterns of the enrolled population relative to the total Indigenous population. The level of VII enrolment (50 per cent nationally as at August 2010) varies across age-sex-remoteness-State/Territory sub-groups and over time which means that the extent of adjustment required varies across jurisdictions and over time. Indigenous rates should also be interpreted with caution due to small population numbers in some jurisdictions.

Source: SCRGSP 2011.

Table 3.10.3: Proportion of people receiving clinical mental health services, by Indigenous status, by state/territory, 2009–10[(a)(b)(c)]

	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	Aust	
	Per cent									Number
Indigenous status										
Indigenous	8.1	10.2	4.7	3.0	6.1	7.2	8.6	1.3	5.6	28,303
Non-Indigenous	6.3	7.0	5.9	5.3	6.3	5.6	5.1	3.2	6.2	1,337,882

(a) Rates are age-standardised to the Australian population as at 30 June 2001.

(b) The Indigenous status rates should be interpreted with caution due to the varying and, in some instances, unknown quality of Indigenous identification across jurisdictions.

(c) Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. Indigenous rates are therefore modelled and should be interpreted with caution. These statistics are not derived from the total Australian Indigenous population, but from those Aboriginal and Torres Strait Islander people who have voluntarily identified as Indigenous to Medicare Australia. The statistics have been adjusted to reflect demographic characteristics of the overall Indigenous population, but this adjustment may not address all the differences in the service use patterns of the enrolled population relative to the total Indigenous population. The level of VII enrolment (51 per cent nationally as at August 2010) varies across age-sex-remoteness-State/Territory sub-groups and over time which means that the extent of adjustment required varies across jurisdictions and over time. Indigenous rates should also be interpreted with caution due to small population numbers in some jurisdictions.

General practitioner encounters

Information about general practitioner encounters is available from the BEACH survey. Mental health-related problems (psychological problems) are among the top five most common types of problems managed at GP encounters with Aboriginal and Torres Strait Islander patients. They were the second most common type of problem managed, behind respiratory diseases, during the period 2005–06 to 2009–10 (AIHW 2011a).

Data for the five year BEACH reporting period April 2006–March 2007 to April 2010–March 2011 are presented in Table 3.10.4.

- In the period April 2006–March 2007 to April 2010–March 2011 there were 5,971 GP encounters with Indigenous patients recorded in the survey, at which 9,196 problems were managed. Of these, 11.3% (1,037) were mental health-related problems (Table 3.10.4).
- Mental health-related problems were managed at a rate of 174 per 1,000 encounters with Indigenous patients.
- After adjusting for differences in age distribution, mental health-related problems were managed significantly more often at GP encounters with Indigenous patients at 1.4 times the rate of encounters with other patients.

Table 3.10.4: Mental health-related problems(a) managed by general practitioners, by Indigenous status of the patient, BEACH years April 2006–March 2007 to April 2010–March 2011(b)(c)

	Number		Per cent of total problems		Crude rate (no per 1,000 encounters)			Age-standardised rate (no. per 1,000 encounters)(d)

Aboriginal and Torres Strait Islander primary health-care services

Information on client contacts with emotional and social well-being staff or psychiatrists in Aboriginal and Torres Strait Islander primary health care services is available from the OATSIH Services Reporting database (AIHW 2012a).

In 2010–11, there were 187,000 client contacts with emotional and social wellbeing staff or psychiatrists, representing 7% of the estimated total clients (AIHW 2012a).

The OSR also collects information on mental health programs run by Indigenous primary health care services.

- Nearly all services (97% or 229) provided information on social and emotional wellbeing issues experienced by their clients. Of these, almost all services (99% or 226) reported that one or more of their clients experienced social and emotional wellbeing issues (AIHW 2012a).

Community mental health care services

For the purposes of the National Community Mental Health Care Database, a contact is defined as the provision of a clinically significant service by specialised mental health service providers for patients or clients, other than those admitted to psychiatric hospitals or designated psychiatric units in acute care hospitals, and those resident in 24-hour staffed specialised residential mental health services where the nature of the service would normally warrant a dated entry in the clinical record of the patient or client in question (AIHW 2010b).

- In 2009–10, there were 6,014,294 (total of Indigenous and non-Indigenous) clients of community mental health care services, of which 430,894 service contacts (7.2%) were for Aboriginal and Torres Strait Islander people (Table 3.10.5).
- There were more service contacts per 1,000 population for Aboriginal and Torres Strait Islander people than for non-Indigenous Australians (842 per 1,000 and 262 per 1,000, respectively) (Table 3.10.5).

Contacts by age and sex

- In 2009–10, compared with non-Indigenous Australians, a higher proportion of Indigenous people in younger age groups (35–44 and younger) had contacts with mental health services. The proportions were lower in the older age groups (45–55 and older), which may, in part, be associated with the differences in age distribution in these populations (the median age of Indigenous Australians is around 21 years compared with 38 years for non-Indigenous Australians (ABS 2011)). For example, 23% and 24% of service contacts for Indigenous Australian males and females were for clients aged between 15 and 24 years compared with 14% and 17% of service contacts for non-Indigenous Australian males and females of the same age. Furthermore, the rate ratio between Indigenous and non-Indigenous rate per 1,000 populations ranged between 1.7 and 4.5 across all age groups (Table 3.10.5).
- Rates of service contacts with community mental health care services were much higher for Indigenous males than Indigenous females (1,061 compared with 629 per 1,000 population), and were highest for Indigenous persons aged 25–34 and 35–44
- In 2009–10, Indigenous Australians had higher rates of community mental health care service contacts across of all age groups compared with non-Indigenous Australians.

Rate ratios were most marked in the 25–34 and 35–44 year age groups where Indigenous persons were 4.5 and 3.6 times more likely, respectively, to be clients of community mental health care services than non-Indigenous persons (Table 3.10.5).

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the p <0.05 level.

(a) These data should be interpreted with caution because of likely under-identification of Indigenous Australians.

(b) Number per 1,000 population based on estimated resident population as at **30 June 2009.**

(c) Rate ratio—Indigenous: non-Indigenous.

(d) Rate difference is equal to Indigenous rate minus non-Indigenous rate.

(e) Includes service contacts for clients for whom age or sex was not stated.

(f) Total rates have been directly age-standardised using the Australian 2001 standard population.

Source: AIHW analysis of National Community Mental Health Care Database.

Contacts by state/territory

The number and rate of service contacts per 1,000 population for Indigenous people vary among the states and territories. This may reflect variations in completeness of Indigenous identification among patients, varying coverage of service contacts for Indigenous people or for the total population, or different patterns of service use by Indigenous and non-Indigenous persons. These rates should be interpreted with caution because there is likely to be an under estimate of the actual number of service contacts for Indigenous clients.

- In 2009–10, the rate of service contacts for clients of community mental health services who identified themselves as being of Aboriginal or Torres Strait Islander origin ranged from 217 per 1,000 in the Northern Territory to 1,767 in the Australian Capital Territory. New South Wales had the highest rate ratio and rate difference in Indigenous to non-Indigenous community mental health service contacts (Table 3.10.6).

Table 3.10.6: Community mental-health-care service contacts per 1,000 population, by Indigenous status and state/territory, 2009–10

Total	**317.6**	**317.7**	**202.4**	**303.8**	**344.8**	**435.2**	**728.4**	**163.6**	**302.5**

(a) Rates were directly age-standardised using the Australian 2001 standard population.

(b) Rate ratio—Indigenous: non-Indigenous.

(c) Rate difference is equal to Indigenous rate minus non-Indigenous.

Note: Shading indicates that the Indigenous identification in the National Community Mental Health Care Database (NCMHCD) in these jurisdictions is in need of improvement. This is based on information provided by state and territory health authorities on the quality of their data in the NCMHCD. Data from these states and territories should be interpreted with caution because of likely under identification of Indigenous Australians.

Source: AIHW analysis of National Community Mental Health Care Database.

Hospitalisations

- For the two year period July 2008 to June 2010, there were 646,051 hospitalisations from mental health-related conditions in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, 24,327 (3.8%) of which were hospitalisations of Aboriginal and Torres Strait Islander people.
- Mental health related conditions were responsible for around 4% of all hospitalisations of Aboriginal and Torres Strait Islander Australians (see indicator 1.18).

Hospitalisations by state/territory

Table 3.10.7 presents hospitalisations for a principal diagnosis of mental health-related conditions in New South Wales, Victoria, Queensland, Western Australia, South Australia, the Northern Territory, Tasmania and the Australian Capital Territory for the two year period from July 2008 to June 2010.

- Over the period from July 2008 to June 2010, in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, Indigenous males were hospitalised for mental health-related conditions at 2.2 times the rate of non-Indigenous males, and Indigenous females were hospitalised for mental health-related conditions at 1.5 times the rate of non-Indigenous females.
- South Australia had the highest Indigenous hospitalisation rate for mental health-related conditions (45 per 1,000), followed by Western Australia (34 per 1,000). These two jurisdictions also had the largest rate differences between Indigenous and non-Indigenous hospitalisations for mental health-related conditions.
- In South Australia, Indigenous Australians were hospitalised for mental health-related conditions at around four times the rate of non-Indigenous Australians. In New South Wales, the Northern Territory and Western Australia rate ratios ranged from 2.2 to 2.5, and in Queensland and Victoria rate ratios were around 1.5.

Table 3.10.7: Hospitalisations for principal diagnosis of mental-health-related conditions, by Indigenous status, sex and state/territory, NSW, Vic, Qld, WA, SA and NT, Tas and ACT, July 2008 to June 2010[(a)(b)(c)(d)]

Males	72	24.5	2,338	6.8	3.6*	17.7*
Females	70	18.1	2,284	6.4	2.8*	11.7*
Persons	142	20.9	4,622	6.5	3.2*	14.4*

* Represents results with statistically significant differences in the Indigenous/other comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification in Health 2010); ICD–10–AM codes F00–F99, G30, G47.0, G47.1, G47.2, G47.8, G47,9, 099.3, R44, R45.0, R45.1, R45.4, R48, Z00.4, Z03.2, Z04.6, Z09.3, Z13.3, Z50.2, Z50.3, Z54.3, Z61.9, Z63.1, Z63.8, Z63.9, Z65.8, Z65.9, Z71.4, Z71.5, Z76.0.

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised and are for New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland only. These six jurisdictions are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(e) Directly age-standardised using the Australian 2001 standard population in five-year age groups to 75+ for NSW, Vic, Qld, WA, SA and NT. Directly age-standardised using the Australian 2001 standard population in five-year age groups to 65+ for Tasmania and the ACT.

(f) Rate ratio—Indigenous: other.

(g) Rate difference Indigenous minus non-Indigenous Australians.

Notes

1. Population estimates based on the 2006 Census.
2. Care types 7.3, 9 and 10 (newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Hospitalisations by ambulatory and non-ambulatory-equivalent

Mental health services can be provided in ambulatory or non-ambulatory settings. Ambulatory mental health care settings range from care provided in the primary care settings through to ambulatory care in hospital-based outpatient services, community-based mental health care and same day admitted patient mental health care in specialised psychiatric and general hospitals. Non-ambulatory mental health care settings include admitted patient mental health care in specialised psychiatric and general hospitals and residential mental health care.

Table 3.10.8 and Figure 3.10.1 present ambulatory-equivalent and non-ambulatory-equivalent mental health-related hospitalisations for Indigenous and non-Indigenous Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory over the two year period from July 2008 to June 2010. Data are for admitted patient from NHMD database. Ambulatory-equivalent and non-ambulatory-equivalent mental health-related hospitalisations are defined using the "Mental Health Flag" variable.

- Between July 2008 and June 2010, there were 3,939 ambulatory-equivalent mental health-related hospitalisations among Indigenous Australians (1,280 with specialised psychiatric care and 2,659 without specialised psychiatric care).
- Over the same period there were 21,158 non-ambulatory-equivalent mental health-related hospitalisations among Indigenous Australians (9,854 with specialised psychiatric care and 11,304 without specialised psychiatric care).
- Rates of ambulatory-equivalent mental health-related hospitalisations were lower for Indigenous Australians than non-Indigenous Australians (rate ratio of 0.6). This was particularly the case for ambulatory-equivalent separations with specialised psychiatric care, with the rate ratio being 0.2. In contrast, the rate of ambulatory-equivalent separations without specialised psychiatric care per 1,000 Indigenous people was almost double that for non-Indigenous Australians (rate ratio of 1.9).
- Rates of non-ambulatory-equivalent mental health-related hospitalisations per 1,000 Aboriginal and Torres Strait Islander people were more than double that for non-Indigenous Australians (rate ratio of 2.2). The rate of such hospitalisations with specialised psychiatric care among Indigenous Australians was 1.6 times that of non-Indigenous Australians. The rate of non-ambulatory-equivalent separations among Indigenous Australians without specialised psychiatric care was over three times that of non-Indigenous Australians.

Table 3.10.8: Ambulatory-equivalent and non-ambulatory-equivalent mental-health-related hospitalisations, by Indigenous status and sex, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010(a)(b)(c)(d)

Figure 3.10.1: Ambulatory-equivalent and non-ambulatory-equivalent mental health-related hospitalisation rates, by Indigenous status, NSW, Vic, Qld, WA, SA and NT, July 2008to June 2010

Average length of stay

Table 3.10.9 presents the average length of stay and total number of bed days for non-ambulatory-equivalent mental health-related hospitalisations for Indigenous and non-Indigenous Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined.

- In the period from July 2008 to June 2010, the average length of stay in hospital for non-ambulatory-equivalent mental health-related hospitalisations was a bit higher for Indigenous Australians than non-Indigenous Australians (9.6 days compared with 8.9 days, respectively).
- For both Indigenous and non-Indigenous Australians, the average length of stay was longer for non-ambulatory-equivalent hospitalisations with specialised psychiatric care than without specialised psychiatric care.
- However, there were differences in average length of stay between Indigenous and non-Indigenous Australians with regard to specialised and non-specialised care. Indigenous Australians tended to stay in hospital slightly longer than non-Indigenous Australians for non-ambulatory-equivalent hospitalisations involving specialised psychiatric care (20.8 compared with 19.2 average days), but experienced shorter stays involving hospitalisations without specialised psychiatric care (2.9 compared with 5.9 average days).

Table 3.10.9: Average length of stay for non-ambulatory-equivalent mental health-related hospitalisations, by Indigenous status and sex, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010[(a)(b)(c)(d)]

Time series analyses

Time series data are presented for the four jurisdictions that have been assessed as having adequate identification of Indigenous hospitalisations for all years from 1998–99 to 2009–10: Queensland, Western Australia, South Australia and the Northern Territory (Table 3.10.10). These four jurisdictions represent approximately 60% of the Indigenous Australian population. New South Wales and Victoria were identified as having adequate identification of Indigenous hospitalisations from 2004–05 onwards, and so they are included in a separate time series analysis (Table 3.10.11).

Note that changes in the level of accuracy of Indigenous identification in hospital records over this period will result in changes in the level of reported hospital separations for Indigenous Australians. Also, changes in access, hospital policies and practices all have an impact on the level of hospitalisation over time. Caution should be used in interpreting changes over time because it is not possible to ascertain whether a change in reported hospitalisation is due to changes in the accuracy of Indigenous identification or real changes in the rates at which Indigenous people are hospitalised. An increase in hospitalisation rates may reflect better hospital access rather than a worsening of health.

Hospitalisations of mental health-related conditions (1998–99 to 2009–10)

Hospitalisation rates, rate ratios and rate differences between Indigenous and non-Indigenous Australians for mental health-related conditions over the twelve year period 1998–99 to 2009–10 are presented in Table 3.10.10 and Figure 3.10.2.

- In Queensland, Western Australia, South Australia and the Northern Territory, there were significant increases in hospitalisation rates for mental health-related conditions among Indigenous females during the period 1998–99 to 2009–10. The fitted trend implies a 57% increase in the rate over the period.
- There were significant declines in hospitalisation rates for mental health-related conditions among non-Indigenous Australians males over the same period, with an average yearly decline in the rate of around 0.1 per 1,000. This is equivalent to a 6.7% decline in the rate over the period.
- There were significant increases in both the hospitalisation rate ratios and rate differences between Indigenous and non-Indigenous Australians over the period 1998–99 to 2009–10 (8.5% increase in the rate ratio and 21% increase in the rate difference for persons over the period). This reflects both a relative and absolute increase in the gap between hospitalisation rates of Indigenous and non-Indigenous Australians for mental health-related conditions over the period 1998–99 to 2009–10.

Table 3.10.10: Age-standardised hospitalisation rates, rate ratios and rate differences for mental health-related conditions, Qld, WA, SA and NT combined, 1998–99 to 2009–10(a)

Figure 3.10.2: Hospitalisation rates, rate ratios and rate differences between Indigenous and other Australians from mental-health-related conditions, Qld, WA, SA and NT combined, 1998–99 to 2009–10

Hospitalisations of mental health-related conditions (2004–05 to 2009–10)

Hospitalisation rates, rate ratios and rate differences between Indigenous and non-Indigenous Australians for mental health-related conditions over the four year period 1998–99 to 2009–10 are presented in Table 3.10.11 and Figure 3.10.3.

- In New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, there were significant increases in hospitalisation rates for mental health-related conditions among Indigenous males during the period 2004–05 to 2009–10. The average yearly increase in the rate was 0.5 per 1,000, which is equivalent to a 9.5% increase over the period. There were also significant changes in hospitalisation rates for mental health-related conditions among Indigenous females over the same period (8.9% increase).
- There were significant increases in both the hospitalisation rate ratios and rate differences between Indigenous and non-Indigenous persons over the period 2004–05 to 2009–10 (5.1% increase in the rate ratio and 17% increase in the rate difference over the period). This reflects both a relative and absolute increase in the gap between hospitalisation rates of Indigenous and non-Indigenous Australians for mental health-related conditions over the period 2004–05 to 2009–10.

Table 3.10.11: Age-standardised hospitalisation rates for mental-health related conditions, rate ratios and rate differences, NSW, Vic, Qld, WA, SA and NT, 2004–05 to 2009–10[(a)]

Public psychiatric hospitals

Information on the number of public psychiatric hospitals in Australia is available from the National Mental Health Establishments Database.

- In 2008–09, there were 16 public psychiatric hospitals in Australia with 2,029 available beds. The majority of hospitals were located in *Major cities* (75% or 12 hospitals) and *Inner regional* areas (19% or 3 hospitals). There were no public psychiatric hospitals located in *Remote* or *Very remote* areas (Table 3.10.12).
- Among jurisdictions, New South Wales reported the highest number of available beds in public psychiatric hospitals (911), although South Australia had the highest number of available beds per 100,000 population (21 beds).
- In 2008–09, there were 140 public acute hospitals with a specialised psychiatric unit or ward. New South Wales and Victoria had the largest number of public acute hospitals with specialised psychiatric units or wards (50 and 31, respectively), while Tasmania and Queensland had the highest number of beds per 100,000 population (26 and 24, respectively) (Table 3.10.8). The majority of public acute hospitals with specialised psychiatric units or wards were located in *Major cities* (67% or 94 hospitals) (Table 3.10.13).

Residential mental health care services

Residential mental health care refers to care provided by a specialised mental health service that:

- employs mental health care-trained staff on–site
- provides rehabilitation, treatment or extended care to residents for whom the care is intended to be on an overnight basis and in a domestic–like environment
- encourages the resident to take responsibility for their daily living activities.

These services include those that employ mental health-trained staff on-site 24 hours per day and other services with less intensive staffing. However, all these services employ on-site mental-health-trained staff for some part of the day. There are no residential mental health care services in Queensland.

- In 2009–10, there were 3,964 residential mental-health-care service episodes provided in Australia, 121 of which (3%) were for Indigenous people (Table 3.10.14).
- Nationally, Indigenous people were 1.5 times more likely than non-Indigenous people to receive a residential mental-health-care service; however rate ratios were substantially higher in South Australia and New South Wales (4.9 and 4.0 respectively).

Table 3.10.14: Residential mental-health-care episodes per 10,000 population, by Indigenous status and state/territory, 2009–10

Total	**0.3**	**4.1**	**. .**	**1.0**	**1.4**	**17.7**	**1.6**	**3.4**	**1.8**

(a) Queensland does not report any government-operated residential mental health services.

(b) Rates were directly age-standardised using the Australian 2001 standard population

(c) Rate ratio—Indigenous: non-Indigenous.

(d) Rate difference is equal to Indigenous rate minus non-Indigenous.

Note: Shading indicates that the Indigenous identification in the National Community Mental Health Care Database (NCMHCD) in these jurisdictions is in need of improvement. This is based on information provided by state and territory health authorities on the quality of their data in the NCMHCD. Data from these states and territories should be interpreted with caution because of likely under identification of Indigenous Australians.

Self-reported data

Self-reported data from the 2004–05 NATSIHS on visiting a health professional for mental-health-related reasons are presented in Tables 3.10.15, 3.10.16 and 3.10.17 below.

- In 2004–05, approximately 12% of Indigenous Australians Persons reported visiting a health professional about their feelings in the four weeks prior to survey (Table 3.10.15).
- The Northern Territory had the highest proportion of Indigenous Australians reporting they visited a health professional about their feelings (17%) followed by Victoria (16%); New South Wales and Queensland had the lowest (both 10%).
- The highest proportion of Indigenous Australians, aged 18 years and over who scored greater than 1 on at least one of the K5 (Kesslor Psychological Distress Scale) items, who reported visiting a professional about their feelings were in *Very remote* areas (14%) followed by *Inner regional* areas (13%) (Table 3.10.16).
- A higher proportion of Indigenous Australians (20%) than non-Indigenous Australians reported visiting an ‘other health professional’ (13%) (Table 3.10.17).

Psychiatrists and psychologists employed in Australia

Information on the number of psychiatrists and psychologists employed in Australia comes from the National Health Workforce Data Set.

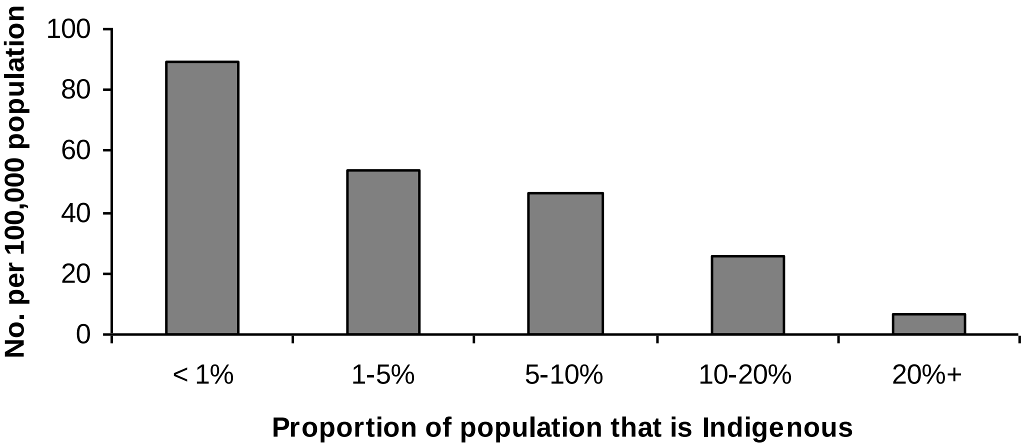
The AIHW Medical Labour Force Survey collected information on the number of psychiatrists in Australia.

- In 2009, it was estimated that 3,005 psychiatrists and 725 psychiatrists-in-training were working in Australia, which represents about one in twenty (5.1%) employed medical practitioners (AIHW 2011a).
- There were 18 FTE psychiatrists (including psychiatrists-in-training) per 100,000 population in Australia in 2009. The rate ranged from 11 FTE per 100,000 in the Northern Territory to 22 per 100,000 in Queensland.
- The rate of FTE psychiatrists per 100,000 population was much higher in *Major cities* (23 per 100,000) than in *Remote* and *Very remote* areas (3 per 100,000). In 2009, 89.5% of FTE psychiatrists (for whom region was reported) worked mainly in the *Major cities*. Once population sizes were taken into account, the FTE psychiatrists per 100,000 population was highest in *Major cities* (23) followed by *Inner regional* (7) and *Outer regional* (5) areas (AIHW 2011a).

Information on psychologists in Australia is available from the AIHW Psychologist Labour Force Survey, the latest of which was conducted in 2002.

The 2002 survey was conducted in five jurisdictions (New South Wales, Victoria, Queensland, South Australia and the Australian Capital Territory). The number of registered psychologists in these jurisdictions comprised around 86% of psychologists registered nationally. Coverage excludes those psychologists whose initial registration occurred during the 12 months preceding the survey. The overall response rate for the five jurisdictions was 56%.

- In 2003, there were 14,073 employed psychologists in the five jurisdictions included in the AIHW survey. The FTE rates of psychologists per 100,000 population for each jurisdiction were estimated to be: New South Wales, 88; Victoria, 95; Queensland, 64; South Australia, 54; and the Australian Capital Territory, 170 (AIHW 2006).
- The FTE rate of employed psychologists was highest in areas where less than 1% of the population was Indigenous (89 per 100,000) and lowest in areas where 20% or more of the population was Indigenous (7 per 100,000) (Table 3.10.18; Figure 3.10.4).



Notes

1. In 2002, 492 employed psychologists did not report the postcode they worked in. Hence the number of employed psychologists stated by region is an underestimate.
2. Data for New South Wales, Victoria, Queensland, South Australia and the Australian Capital Territory only.
3. FTE is based on 35 hours per week.

Source: AIHW analysis of Psychologist Labour Force Survey, 2002–03.

Figure 3.10.4: FTE employed psychologists per 100,000 population, by proportion of Indigenous population living in an area, 2002–03

Table 3.10.18: FTE employed psychologists per 100,000 population, by proportion of Indigenous population living in an area, 2002–03

Proportion of the population that is Indigenous	FTE per 100,000 population
< 1%	89
1–5%	54
5–10%	46
10–20%	26
20%+	7

Notes

1. In 2002, 492 employed psychologists did not report the postcode they worked in. Hence the number of employed psychologists stated by region is an underestimate.
2. Data for New South Wales, Victoria, Queensland, South Australia and the Australian Capital Territory only.
3. FTE is based on 35 hours per week.

Additional information

Supported Accommodation Assistance Program

In 2010–11, 12% of both Indigenous and non-Indigenous clients of the Supported Accommodation Assistance Program with mental health-related closed support periods were identified as Aboriginal or Torres Strait Islander Australians. After adjusting for differences in age, this was five times the rate for non-Indigenous Australians (Table 3.10.19).

Table 3.10.19: Supported Accommodation Assistance Program clients with mental health-related closed support periods by Indigenous status, 2010–11

	Clients			Closed support periods		
	Number[(a)(b)]	Per cent of clients[(b)]	Rate[(b)(c)] (per 100,000 population)	Number[(a)(b)]	Per cent of support periods[(b)]	Rate[(b)(c)] (per 100,000 population)
Indigenous status						
Indigenous Australians	2,107	11.8	399.4	2,605	11.0	501.5
Non-Indigenous Australians	15,715	88.2	73.4	21,089	89.0	98.5
Total number	**17,822**	**100**	**84.3**	**23,694**	**100.0**	**116.4**

(a) The number of clients for Indigenous status, and number of closed support periods for Indigenous status, were missing and/or not reported for nearly 3.5% of the total.

(b) The numbers, percentages and rates shown do not include those clients or closed support periods for which Indigenous identification was missing.

(c) Rates were calculated using population census 2006. Other population, which was equal total Australian population minus Indigenous population, were used to calculate rate for non-Indigenous Australia.

Source: Supported Accommodation Assistance Program Client Collection.

Data quality issues

Medicare data

MBS items

The MBS items included in this measure have been introduced over the last few years with the child health check item commencing in May 2006. The take-up of new MBS items is influenced by the speed at which practitioners and the population become aware of the new items and how to use them. Also take-up can be influenced by administrative processes and the time taken to change computer systems to incorporate these new items.

Standard Indigenous status question

In November 2002, the ABS standard question on Indigenous identification was included on Medicare enrolment forms. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Under-identification

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete. There were around 339,310 people who had identified as Aboriginal and/or Torres Strait Islander in this database at May 2012; around 59% of the estimated Aboriginal and Torres Strait Islander population (AHMAC 2012). There has been a rapid expansion in the number of enrolees who identified as Aboriginal and/or Torres Strait Islander, from 47,200 people in August 2004.

Readers should note the following caveats to the Medicare voluntary Indigenous Identifier (VII) adjustment methodology:

- Estimates generated by the adjustment methodology for a given period will vary according to the point in time at which they are calculated, as the adjustment factors will be updated regularly to account for the ongoing change in the population coverage of the VII sample.
- There are inherent uncertainties in the current ABS Indigenous population estimates, and they are therefore described by the ABS as ‘experimental estimates and projections’. The ABS Indigenous population estimates after 2006–07 are experimental projections, based on a number of assumptions about future levels of fertility, mortality and migration. The projections are not predictions or forecasts, but are illustrations of the growth and change in population that would occur if these assumptions were to prevail over the projection period. There can be no certainty that any particular outcome will be realised, or that future outcomes will necessarily fall within the projected ranges.
- The propensity to identify as Aboriginal and/or Torres Strait Islander varies according to the motivations of the individual and the perceived uses of the data in question. For example, it is possible that there are some Aboriginal and Torres Strait Islander people who are registered with the VII but who do not identify as Indigenous for the purposes of the Census, or vice versa.
- In some areas, particularly remote and very remote areas, there is a portion of the Indigenous population that does not ever use the Medicare system. It is therefore possible that the adjustment methodology could overestimate Medicare use by the Indigenous population.

- As the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could be biases in the data that are not addressed by the adjustment methodology.

General Practitioner Data (BEACH)

Information about general practitioner encounters is available from the Bettering the Evaluation and Care of Health (BEACH) survey. The BEACH data on Indigenous Australians should be treated with care. First, the sample has not been designed to produce statistically significant results for population subgroups such as Indigenous Australians. Second, the identification of Indigenous Australians is not complete. Although the questionnaire contains an Indigenous identifier, it is unknown whether all GPs ask their patients this question. In the BEACH survey, 'not stated' responses to the Indigenous identification question are often higher than the 'yes' responses. It can be assumed, therefore, that the survey consistently undercounts the number of Indigenous Australians visiting general practitioners. Further detailed analyses of this issue are covered in *General practice in Australia, heath priorities and policies 1998 to 2008*, (Britt & Miller 2009:101):

'The findings of a BEACH substudy confirmed this suspected under-identification. In the data period reported here, 1.4% of patients encountered identified themselves as Indigenous. In contrast, in a BEACH substudy that asked 9,245 patients a complete set of questions about their cultural background (including Indigenous status) 2.2% (95% CI: 1.6–2.9) of respondents identified themselves as Indigenous (Britt et al. 2007). This rate is similar to the ABS estimates of Indigenous Australians as a proportion of the total population (ABS 2006).

However, the BEACH substudy included Indigenous Australians seen at Community Controlled Health Services funded through Medicare claims, and the estimate of 2.2% could have been an overestimate for the proportion of encounters that are with Indigenous patients in general practice as a whole. Deeble et al. (2008) conducted further investigations on this data and estimated that the BEACH encounter identification was an underestimate of about 10%, and that a more reliable estimate of the Indigenous population would be about 1.6% of all encounters (Deeble et al. 2008).

The findings of these studies are that some GPs are not routinely asking patients at the encounter about their Indigenous status, even when this is a variable specifically collected for each patient encountered, as it is in BEACH encounter data.'

OATSIH Service Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012a).

National Community Mental Health Care Database

There is some variation in the types of service contacts included across jurisdictions. For example, some jurisdictions include written correspondence as service contacts while others do not. The Northern Territory estimates that there could be a deficit of between 25–35% of service contact records. Coverage for most other jurisdictions is estimated to be between 95–100%.

The numerator includes people who receive a service in one jurisdiction but normally reside in another. There will be some mismatch between numerator and denominator in areas with cross-border flows.

Indigenous under-identification

The Indigenous status data should be interpreted with caution due to the varying and, in some instances, unknown quality of Indigenous identification across jurisdictions. The Other Australians category includes contacts where Indigenous status was missing or not reported (around 7% of all contacts). All states and territories use the standard ABS question of Indigenous status.

National Hospital Morbidity Data

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

Residential Mental Health Care

The scope for this collection is all episodes of residential care for residents in all government-funded and operated residential mental health services in Australia, except those residential care services that are in receipt of funding under the *Aged Care Act 1997* and subject to Commonwealth reporting requirements (that is, they report to the System for the Payment of Aged Residential Care collection). The inclusion of government-funded, non-government-operated services and services that are not staffed for 24 hours a day is optional. Queensland does not have any in-scope government-operated residential mental health services and therefore does not report to this collection.

For the 2009–10 data collection, all but 8 of the facilities reported had mental health trained staff on-site 24 hours a day. Data from 11 non-government organisations were also included in the 2009–10 collection. All jurisdictions reported 100% data coverage in 2009–10.

Data from the NRMHCD on Indigenous status should be interpreted with caution because of the varying quality and completeness of Indigenous identification across all jurisdictions. No formal assessment of the level of under-identification has been conducted for this data collection, however Western Australia, South Australia, the Northern Territory and the Australian Capital Territory considered their Indigenous status data of acceptable quality in 2009–10. In Victoria and New South Wales, there has been an increasing focus on collecting Indigenous data more accurately in accordance with best practice guidelines. Tasmania reported that the quality of the Indigenous status data collected does require improvement and is being addressed with the implementation of a new mental health information system (AIHW 2011b).

National Health Workforce Data Set (NHWDS)

The Australian Health Practitioner Regulation Agency (AHPRA), in conjunction with the national boards, is responsible for the national registration process for 14 health professions. The data from this annual registration process, together with data from a workforce survey that is voluntarily completed at the time of registration, forms the National Health Workforce Dataset (NHWDS). Data in the NHWDS includes demographic and employment information (for example labour force status, location of main job, area of practice, work setting) for registered health professionals.

AIHW Medical Labour Force Survey

The AIHW Medical Labour Force Survey is conducted on an annual basis. Survey responses are weighted by state, age and sex to produce state and territory and national estimates of the total medical labour force. Benchmarks for weighting come from registration information provided by state and territory registration boards.

The response rates to this survey can vary from year to year and across jurisdictions, but have stayed fairly stable over the five years to 2004. Note that the questionnaires have varied over time and across jurisdictions. Mapping of data items has been undertaken to provide time series data. However, because of this, and the variation in response rates, some caution should be used in interpreting change over time and differences across jurisdictions.

More detailed information about how these surveys were conducted is available from the *Medical labour force 2009* (AIHW 2011a).

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The 2004–05 NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

Supported Accommodation Assistance Program (SAAP)

The SAAP collection is an administrative data collection and therefore cannot be used as an indicator for the Australian population. Due to the definition of homelessness for SAAP, there is no way to distinguish whether a person who receives SAAP support was at imminent risk of homelessness or was actually homeless. Therefore, SAAP cannot be used as an indicator for the Australian homeless population.

SAAP also requires valid consent to be given each time a client is supported (support period) in order to collect all the client level and support period level information. However, if consent is not given then only a limited about of information can be collected about the particular client and their support period and this client cannot be linked with any other support periods they may have had.

The Indigenous status question for SAAP requires consent to collect information and is answered by the client and must be recorded as stated by the client, irrespective of the workers perception based on appearance or other factors. This may lead to an undercount of Indigenous SAAP clients if the client does not give consent or does not identify as being of Aboriginal or Torres Strait Islander origin.

A weighting model has been developed to adjust for agency non-participation, client non-consent and client mixed consent in SAAP data. These weights are applied to the majority of SAAP tables and help reflect the true usage of SAAP services across Australia.

From July 2011, the SAAP NDC was replaced by the Specialist Homelessness Services Collection (SHSC). The SHSC was developed by the AIHW in collaboration with the Australian Government Department of Families, Housing, Community Services and Indigenous Affairs and relevant departments of all state and territory governments.

Key differences between the SAAP NDC and SHSC include the expanded scope of agencies included in the SHSC, to agencies funded under the National Affordable Housing Agreement (NAHA) and National Partnership Agreement on Homelessness (NPAH); the inclusion of children as clients in their own right in SHSC (whereas accompanying children were recorded on their parent's form in SAAP NDC); and the monthly collection of client information and services provided for the SHSC (whereas SAAP NDC information was only collected at the end of a support period).

First results of the new SHSC from the first quarter of data collection—July to September 2011 were released in April 2012. This reported that almost one-fifth (19%) of clients who provided information on their Indigenous status were Aboriginal and/or Torres Strait Islander, while 12% of clients did not have information on Indigenous status recorded (AIHW 2012b). This is higher than the 5% of not stated responses reported for the last year of the SAAP NDC. However it should be noted that analysis of the September quarter 2011 SHSC data identified some implementation issues. In particular, the rate of invalid/'don't know'/missing responses was high for many data items. It is expected that rates of missing/not stated information will greatly reduce over the next few quarters of data collection as implementation issues are resolved.

With respect to agency participation rates in the new SHSC, 93% of relevant agencies returned support period data for at least one month in the September quarter 2011. This compares favourably with the SAAP agency participation rate, which was 90% in 2010–11 and 92% on average between 2001–02 and 2010–11.

List of tables

List of figures

3.11 Access to alcohol and drug services

Access to alcohol and drug services by Indigenous Australians, expressed as percentages, rates, rate ratios and rate differences.

Data sources

Data related to access to alcohol and drug services come from the OATSIH Services Reporting data collection (OSR), the Alcohol and Other Drug Treatment Services National Minimum Data Set (AODTS-NMDS), the National Hospital Morbidity Database, the Bettering the Evaluation and Care of Health (BEACH) survey, and the National Opioid Pharmacotherapy Statistics Annual Data (NOPSAD) collection.

OATSIH Services Reporting data collection (OSR)

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Alcohol and Other Drug Treatment Services National Minimum Data Set (AODTS–NMDS)

The AODTS–NMDS is a collection of data from all publicly funded (at state, territory and/or Australian Government level) government and non-government agencies that provide one or more specialist alcohol and/or other drug treatment services. The National Minimum Data Set (NMDS) counts treatment episodes completed during the collection period.

There is a diverse range of alcohol and other drug treatment services in Australia and not all of these are in the scope of the AODTS–NMDS. Clients receiving services that are funded solely by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) as Indigenous Substance Use Services, Aboriginal primary health care services, Aboriginal medical services and community controlled health services are not currently included in the scope of the AODTS-NMDS.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

Bettering the Evaluation and Care of Health (BEACH) survey

Information about encounters in general practice is available from the BEACH survey, which was conducted by the AIHW Australian General Practice Statistics and Classification Unit until 2008–09, and by the Family Medicine Research Centre, University of Sydney in collaboration with the AIHW in 2009–10 and 2010–11. On 30 June 2011, the AIHW ceased its involvement in the BEACH program and ceased publishing annual BEACH reports. The survey continues to be run and the results are now published by the University of Sydney. The most recent annual reports can be found at http://ses.library.usyd.edu.au/handle/2123/7771.

Information is collected from a random sample of approximately 1,000 general practitioners (GPs) from across Australia each year. A sample of 100 consecutive GP–patient encounters is collected from each GP.

The number of Indigenous patients identified in the BEACH survey is likely to be underestimated because some GPs might not ask the question on Indigenous status, or the patient may choose not to identify themselves (AIHW 2002).

Before the late inclusion of a 'not stated' category of Indigenous status in 2001–02, 'not stated' responses were included with non-Indigenous encounters. Since then, GP encounters for which Indigenous status was not reported have been included with encounters for non-Indigenous people under the 'other' category.

Data are presented for the 5-year period 2006–07 to 2010–11, during which there were around 6,000 GP encounters with Aboriginal and Torres Strait Islander patients recorded in the survey, representing 1.2% of total GP encounters.

National Opioid Pharmacotherapy Statistics Annual Data (NOPSAD)

The National Opioid Pharmacotherapy Statistics Annual Data (NOPSAD) collection is an administrative by-product collection (that is, secondary use). Data are collated in each jurisdiction from information already collected for the purposes of administering or providing a service (that is, primary use).

The main purpose of the current NOPSAD collection is to report jurisdictional data on the number of clients accessing pharmacotherapy for the treatment of opioid dependence, the number of prescribers participating in the delivery of pharmacotherapy treatment, and quantitative information about the prescribing sector. From the collection, national information on pharmacotherapy can be reported.

In 2005, the Australian Institute of Health and Welfare (AIHW) took on the responsibility for managing, analysing and reporting on the NOPSAD collection.

The collection includes information on client's Indigenous status. Currently Victoria, Western Australia, Tasmania and the Northern Territory are unable to provide data on the Indigenous status of clients receiving pharmacotherapy services.

Data Analyses

Aboriginal and Torres Strait Islander primary health-care services

- In 2010–11, almost 50% of Aboriginal and Torres Strait Islander primary health-care services offered drug and alcohol preventative health care programs (Table 3.11.1).
- Twenty six per cent of services offered group activities for the treatment or prevention of alcohol use, 34% offered group activities relating to tobacco use and 17% offered group activities for other types of substance use (Table 3.11.2).

Table 3.11.1: Proportion of Aboriginal and Torres Strait Islander primary health-care services that offered drug and alcohol preventative health care programs, 2010–11

Preventative health care programs	Per cent
Drug and alcohol programs	49.1
Total Number of Primary Health Care Services	**234**

Source: AIHW OSR data collection.

Table 3.11.2: Proportion[(a)] of Aboriginal and Torres Strait Islander primary health-care services that ran health promotion/prevention group activities during 2010–11

Health promotion/prevention group activities	Per cent
Alcohol use treatment/prevention groups	26.1
Tobacco use treatment/prevention groups	33.6
Other substance use treatment/prevention groups[(b)]	17.1

(a) Two hundred and eleven of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided information on group activities offered by the service. The percentages in the table are calculated as a proportion of these 211 services.

(b) Other groups activities refer to other health group activities provided by respondent Aboriginal and Torres Strait Islander primary health care services

Source: AIHW OSR data collection.

Programs/activities provided

Aboriginal and Torres Strait Islander stand- alone substance use services offer a range of programs and activities to support their communities. Information from the OSR on selected programs and activities provided is presented below.

- Of services that addressed drug and alcohol use, all provided information or education and around 90% provided case management or individual counselling. Other common services provided included: referrals, relationship or social skills training, support groups, group counselling, community education or activities, support for clients accessing mainstream services, cultural activities, and general living skills (Table 3.11.3).
- Of substance-use-specific services that ran selected group activities, 81% provided alcohol use groups, 62% offered tobacco use groups, and 70% provided other substance use groups. Seventy seven per cent of services ran men's groups, 66% provided women's groups and 34% offered groups for young people (Table 3.11.4).

Table 3.11.3: Proportion of Aboriginal and Torres Strait Islander primary health-care services conducting selected drug and alcohol service counselling approaches and cultural activities, 2010–11

Service	Per cent
Information/education	100.0
Case management	91.8
Individual counselling	91.8
General living skills	81.6
Cultural activities	79.6
Support for clients accessing mainstream services	87.8
Crisis intervention	67.3
Community education/activities	85.7
Group counselling	77.6
Support groups	73.5
Relationship/social skills training	77.6
Detoxification support & referral	55.1
Referral	71.4
Telephone counselling	61.2
School education & visits	55.1
Welfare/emergency relief	42.9
Management of Hepatitis C	30.6
Medication detox	24.5
Non-medicated detox	32.7
Tobacco control program	40.8
Mobile assistance program/night patrol	20.4
Needle exchange	4.1
Methadone management	8.2
Other substance use services	18.4
Total number of services addressing substance use	**49**

Substance-use specific services

- In 2010–11, the most common types of program information provided by Indigenous substance-use specific services were community-based education and prevention and advocacy (all 84%) and non-residential counselling/rehabilitation (78%) (Table 3.11.5).
- Detoxification and sobering up centres and programs (both 25%), information on mobile assistance patrols (22%) and residential respite (12%) were the least likely to be provided by these services.

Table 3.11.5: Proportion of Aboriginal and Torres Strait Islander substance-use services providing specific program information, 2010–11

Services providing program information	Per cent
Residential treatment/rehabilitation	61.2
Residential respite	12.2
Detoxification	24.5
Sobering-up centre/program	24.5
Program for clients diverted from the legal system	73.5
Non-residential counselling/rehabilitation	77.6
Community-based education and prevention	83.7
Advocacy	83.7
Mobile assistance patrol/night patrol	22.4
Other	24.5
Total number of services[(a)]	**49**

(a) A service can provide more than one program therefore total number of service does not reflect the sum of above.

Source: AIHW OSR data collection.

Clients of alcohol and other drug treatment services

- In 2010–11, there were 19,628 treatment episodes involving Indigenous clients of alcohol and other drug treatment services (Table 3.11.6). This represented 13% of all clients, far exceeding the proportion of Indigenous people in the Australian population aged 10 years and over (2.2%) (AIHW 2012a).
- The proportion of treatment episodes was higher for Indigenous males (8%) than females (5%).
- Indigenous clients were generally younger than non-Indigenous clients. The proportion of episodes for Indigenous clients in the 10–19 and 20–29 year age groups was 21% and 30% respectively, compared with 11% and 27% for non-Indigenous clients. This may, in part, reflect the younger age structure of the Indigenous population (AIHW 2012a).

Clients of substance-use specific services

- In 2010–11, 3,634 residential treatment/rehabilitation episodes of care were provided to Indigenous and non-Indigenous clients by Aboriginal and Torres Strait Islander stand-alone substance use services. Approximately 85% (3,085) of these episodes were provided to Indigenous clients.
- Three out of four (71%) of the residential treatment/rehabilitation episodes of care in 2010–11 were provided to males. Indigenous males aged 19 years and over represented just over half (53%) of recipients of residential treatment/rehabilitation episodes of care (Table 3.11.7).
- In 2010–11, there were approximately 14,606 sobering-up/residential respite/short-term care episodes of care provided to Indigenous and non-Indigenous clients by Aboriginal and Torres Strait Islander stand- alone substance use services. Almost all (99%, 14,606) of these episodes were provided to Indigenous clients.
- Across all age groups, the majority of sobering-up/residential respite/short-term episodes of care were provided to males. Indigenous with unknown age represented the largest group (53%, 7,785) of recipients of sobering-up/residential respite/short-term episodes of care (Table 3.11.7).
- In 2010–11, 70,666 other episodes of care (non-residential/follow-up/aftercare), were provided to Indigenous and non-Indigenous clients by Aboriginal and Torres Strait Islander substance-use disorder specific services. Over three-quarters (74%, 52,465) of these episodes were provided to Indigenous clients.

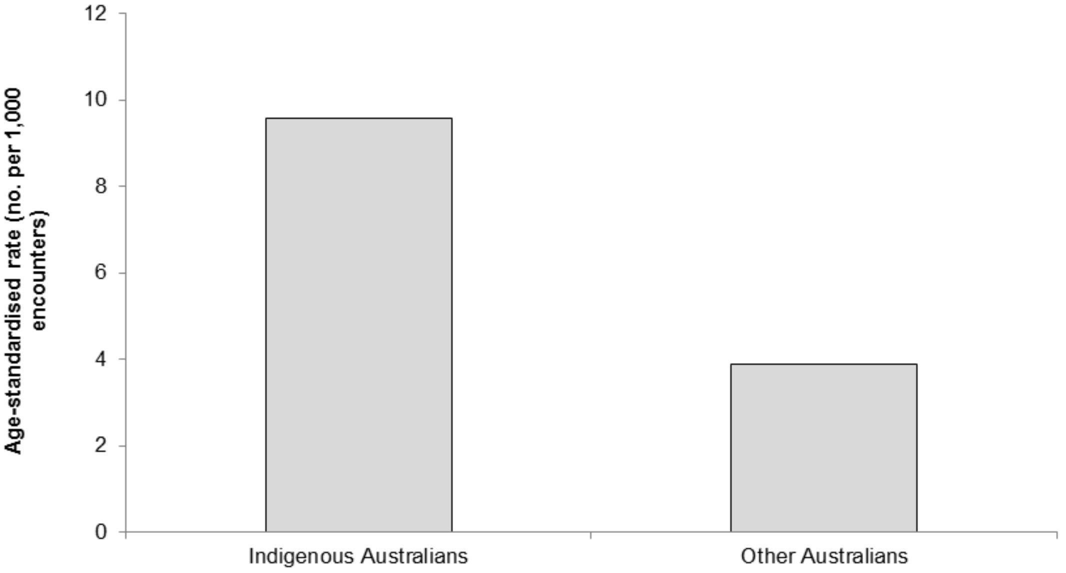
Hospitalisations due to alcohol or drug use

- Between June 2008 and June 2010, in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined, there were 7,763 hospitalisations of Indigenous people with a principal diagnosis relating to alcohol use (See Indicator 2.16, Table 2.16.18).
- Indigenous people were hospitalised at 4 times the rate of non-Indigenous people for alcohol related conditions.
- Over the same period, in the jurisdictions highlighted above, there were 4,537 hospitalisations of Indigenous people with a principal diagnosis relating to drug use (See Indicator 2.17, Table 2.17.11).
- Indigenous people were 2.3 times more likely than non-Indigenous people to be hospitalised for drug related conditions.

Alcohol counselling provided by general practitioners

- In the five year period from April 2006–March 2007 to April 2010–March 2011, the rate of general practitioner encounters for alcohol advice or counselling for Indigenous people was 2.5 times the rate of encounters for non-Indigenous people (Figure 3.11.1 and Indicator 3.07, Table 3.07.4).



Note: IPCP-2 codes defining counselling/ advice alcohol P45005, P58009.

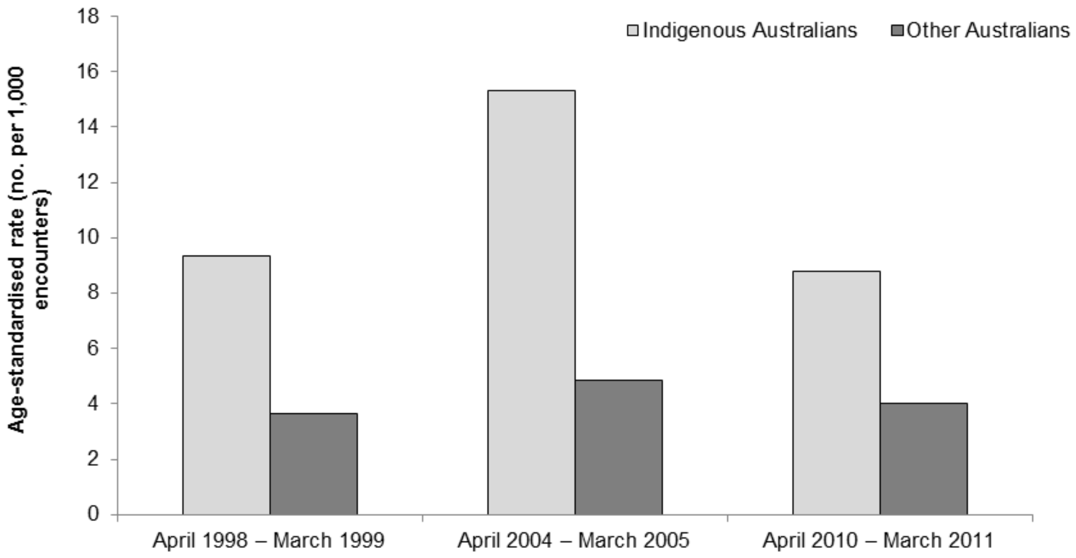
Figure 3.11.1: Counselling/advice on alcohol provided by general practitioners, by Indigenous status, BEACH Years April 2006–March 2007 to April 2010–March 2011

- Data provided on three individual BEACH years between 1998–99 and 2010–11 for counselling/advice on alcohol shows a fluctuation in rates of GP encounters with both Indigenous and other patients. The rate of GP encounters for Indigenous patients was 9.3 per 1,000 in April 1998–March 1999, which increased to 15.3 per 1,000 in April 2004–March 2005, and then declined to 8.8 per 1,000 in April 2010–March 2011. A similar pattern was observed for Other Australians (Figure 3.11.2 and Indicator 3.07, Table 3.07.5).



Note: IPCP-2 codes defining counselling/ advice alcohol P45005, P58009.

Figure 3.11.2: Counselling/advice on alcohol provided by general practitioners, by Indigenous status, BEACH years April 1998–March 1999, April 2004–March 2005 and April 2010–March 2011

Pharmacotherapy clients

- On a snapshot day in 2010, for jurisdictions where data on Indigenous status are available (New South Wales, Queensland, South Australia and the Australian Capital Territory), there were 2,591 Indigenous pharmacotherapy clients (clients receiving methadone, buprenorphine, and buprenorphine/naloxone). This represented 9% of all clients (Table 3.11.8).
- While the number of Indigenous clients has increased substantially since 2006 (from 1,662 to 2591 in 2010), the proportion has increased only marginally (rising from 8% in 2006 to 9% in 2010).

Table 3.11.8: Number of pharmacotherapy clients[(a)] on a 'snapshot/specified' day by Indigenous status and jurisdiction, NSW, Qld, SA, ACT, 2006–2010[(b)(c)(d)]

Data quality issues

OATSIH Services Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012b).

Alcohol and Other Drug Treatment Services National Minimum Data Set (AODTS–NMDS)

There is a diverse range of alcohol and other drug treatment services in Australia and not all of these are in the scope of the Alcohol and Other Drug Treatment Services National Minimum Data Set (AODTS–NMDS). Clients receiving services that are funded solely by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) as Indigenous Substance Use Services, Aboriginal primary health–care services, Aboriginal medical services and community-controlled health services are not included in the AODTS–NMDS (these services contribute to an alternative reporting mechanism).

Each jurisdiction has differing policy and administrative features that have an impact on the quality of data collected. National data are affected by variations in service structures and collection practices between states and territories and care should be taken when making comparisons between them. Also, the AODTS–NMDS has been implemented in stages, so comparisons across years, particularly the earlier years of the collection, need to be made with caution. Not all jurisdictions were able to provide data from the beginning of the collection and not all elements have been reported from the same time (see *Alcohol and other drug treatment services in Australia 2010–11: report on the National Minimum Data Set* (AIHW 2012a) for further information).

As a unit of measurement, the 'closed treatment episode' used in the AODTS–NMDS cannot provide information on the number of clients who access publicly funded alcohol and other drug treatment, nor can it provide information on the extent of concurrent, sequential or recurrent service use. This is because it is possible for a single individual to access more than one service at a time, for different treatments and for different substance use problems. A new data element called a statistical linkage key will be included in the 2012–13 collection. This new element will allow the number of clients accessing treatment to be estimated. A statistical linkage key would also facilitate a greater range of analysis to provide information on patterns of service use, treatment pathways and the characteristics of groups of clients and agencies.

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

Bettering the Evaluation and Care of Health (BEACH) survey

Information about general practitioner encounters is available from the Bettering the Evaluation and Care of Health (BEACH) survey. The BEACH data on Indigenous Australians should be treated with care. First, the sample frame has not been designed to produce statistically significant results for population subgroups such as Indigenous Australians. Second, the identification of Indigenous Australians is not complete. Although the questionnaire contains an Indigenous identifier, it is unknown whether all GPs ask their patients this question. In the BEACH survey, 'not stated' responses to the Indigenous identification question are often higher than the 'yes' responses. It can be assumed, therefore, that the survey consistently undercounts the number of Indigenous Australians visiting general practitioners. Further detailed analyses of this issue are covered in *General practice in Australia, heath priorities and policies 1998 to 2008*, (Britt & Miller 2009:101):

'The findings of a BEACH substudy confirmed this suspected under-identification. In the data period reported here, 1.4% of patients encountered identified themselves as Indigenous. In contrast, in a BEACH substudy that asked 9,245 patients a complete set of questions about their cultural background (including Indigenous status) 2.2% (95% CI: 1.6–2.9) of respondents identified themselves as Indigenous (Britt et al. 2007). This rate is similar to the ABS estimates of Indigenous Australians as a proportion of the total population (ABS 2006).

However, the BEACH substudy included Indigenous Australians seen at Community Controlled Health Services funded through Medicare claims, and the estimate of 2.2% could have been an overestimate for the proportion of encounters that are with Indigenous patients in general practice as a whole. Deeble et al. (2008) conducted further investigations on this data and estimated that the BEACH encounter identification was an underestimate of about 10%, and that a more reliable estimate of the Indigenous population would be about 1.6% of all encounters (Deeble et al. 2008).

The findings of these studies are that some GPs are not routinely asking patients at the encounter about their Indigenous status, even when this is a variable specifically collected for each patient encountered, as it is in BEACH encounter data.'

The National Opioid Pharmacotherapy Statistics Annual Data (NOPSAD) collection

In 2005, the Department of Health and Ageing (DoHA) commissioned the Australian Institute of Health and Welfare (AIHW) to manage the NOPSAD collection, including the analysis and reporting of pharmacotherapy treatment data. A set of agreed standards for reporting were developed in consultation with states and territories, and the NOPSAD collection was developed. While states and territories strive to report data consistent with agreed standards, the NOPSAD collection is not a national minimum data set and some discrepancies exist in the ways in which data are reported.

Each state and territory uses a slightly different method to collect data about the pharmacotherapy used to treat those with opioid dependence. These are driven by differences between the states and territories in relation to legislation, information technology systems and resources. The differences may result in discrepancies when comparing one state or territory with another. See the National Opioid Pharmacotherapy Statistics Annual Data collection: 2011 report (AIHW 2012c) for more information.

New South Wales is unable to differentiate between clients prescribed buprenorphine and buprenorphine–naloxone. Clients prescribed buprenorphine–naloxone are counted under buprenorphine.The collection includes information on client's Indigenous status. Currently Victoria, Western Australia, Tasmania and the Northern Territory are unable to provide data on the Indigenous status of clients receiving pharmacotherapy services.

3.12 Aboriginal and Torres Strait Islander people in the health workforce

Number and proportion of Aboriginal and Torres Strait Islander Australians in the health workforce

Data sources

Census of Population and Housing

The Census of Population and Housing is conducted by the ABS at 5-yearly intervals, and is designed to include all Australian households. The Census uses the ABS standard Indigenous status question for each household member.

The 2011 Census is the most recent, however data for the Indigenous population were not released at the time of writing this report. Therefore data included in this report comes from the 2006 Census. In 2006, the ABS enhanced the sample for the Post-Enumeration Survey to include remote areas. The measured undercount for Indigenous Australians was 11.5%.

Analyses

Aboriginal and Torres Strait Islander health workforce

Data on the number and proportion of Indigenous Australians employed in health-related occupations in 1996, 2001 and 2006 are presented in Table 3.12.1 below.

- In 2006, there were 5,536 Indigenous Australians employed in health-related occupations, which represented 1% of the total health workforce (Table 3.12.2).

Health workforce by occupation

- During the period 1996 to 2006 the number of Indigenous health workers employed in most health occupations increased significantly. The largest increase was observed in health diagnostic and promotion professionals: in 1996 there were 164 Indigenous health workers; this increased to 638 by 2006 (a 289% increase over the period). The second largest increase was allied health professionals (for example psychologists and physiotherapists): 179 were employed in 1996; this increased to 441 in 2006 (a 146% increase over the period).
- In 2006, out of the combined total of Indigenous health workers (5,536), there were 1,736 Indigenous people working in occupations classified as ‘other’, including a substantial amount of nursing support workers and personal care workers. Following this, the next largest occupations were nurses (including midwives and mothercraft nurses) (1,449), and Aboriginal and Torres Strait Islander health workers (966). Aboriginal and Torres Strait Islander health workers may be employed as specialists in areas such as alcohol use, mental health, diabetes, eye and ear health, sexual health, or they may work as generalist members of primary care teams, or as hospital liaison officers.

* Represents results that are statistically significant at the p<0.05 level.

(a) Average period change determined using regression analysis. Per cent change between the reporting periods 1996 and 2006 based on the average annual change over the period.

(b) Rate per 10,000 measures the health workforce available (numerator) to service the population (denominator). Denominator used in rates is the 2006 total population by Indigenous status minus those where occupation is not stated.

(c) Rate difference is non-Indigenous rate minus the Indigenous rate.

(d) Both 2001 and 2006 figures include midwifery and nursing professional n.f.d.

(e) Generalist medical practitioner includes general medical practitioner and resident medical practitioner, and specialist physician (general medicine).

(f) The 2006 figure includes Anaesthetist, Pathologist, Psychologist, Neurosurgeon, Medical Practitioners n.f.d. 2001 figure includes Emergency Medical Specialist, Obstetrician and Gynaecologist, Pathologist, Radiologist, Psychiatrist, Surgeon (General), Medical Practitioners nfd, and 1996 figure includes Specialist Medical Practitioner.

(g) The 2006 figure includes clinical psychologist, psychotherapist, educational psychologist, organisational psychologist, psychologist n.f.d. and psychologist, n.e.c. However, both the 1996 and 2001 figures are clinical psychologist and psychotherapist combined.

(h) The 2006 figure includes chiropractor, osteopath, homeopath, naturopath, complementary health therapist n.e.c. 2001 figure includes chiropractor and naturopath and the 1996 figure includes chiropractor and natural therapy professional.

(i) Health promotion officer could not be identified separately in 2001 and 1996 due to different occupation classifications. These were included in community worker in 2001 and 1996 and not included in the table.

(j) Other health diagnostic and promotion professional includes health diagnostic and promotion professional, n.e.c. The 2006 figure also includes health professional n.f.d. and health diagnostic and promotion professional, n.f.d.

(k) The 2006 figure includes medical administrator only. Health and welfare services manager, n.e.c. and health and welfare services manager, n.f.d. were included in other. 2001 figure is for medical administrator but not published separately due to quality issues and has been included in other. The 1996 figure is for medical administrator.

(l) Nursing support worker and personal care worker includes therapy aide, in 2006 includes hospital orderly, which in 2001 and 1996 was grouped with nursing assistant and personal care assistant occupations because there was no such a category.

(m) The 2006 figure includes medical laboratory scientist, counsellor n.e.c., medical laboratory technician, anaesthetic technician, cardiac technician, operating theatre technician, pharmacy technician, medical technicians n.e.c., optical dispenser, optical mechanic, diversional therapist, massage therapist, personal carer and assistant n.f.d., special care worker n.f.d., natural remedy consultant.

(n) The 2001 figure includes health information manager, medical laboratory scientist, medical technical officer, primary products inspector, anatomist or physiologist, safety inspector, admissions clerk, weight loss consultant, massage therapist, natural remedy consultant.

Note: Numbers less than 10 are considered too unreliable for general use due to the impact of randomisation of small cell values to avoid the release of confidential data. Totals may differ and may not equal the sum of components because of randomisation.

Source: AIHW analysis of the ABS census data.

Health workforce by age and sex

- In 2006, the majority of Indigenous people employed in the health workforce were aged 35–44 years (1,673 people). The proportion of health workers who were Indigenous was highest among those aged 15–24 years (1.4%) and lowest among those aged 65 years and over (0.4%) (Table 3.12.2).
- Indigenous females represented a higher proportion of the health workforce than Indigenous males across all age groups (Table 3.12.3).

Indigenous health workforce by state/territory

- In 2006, the proportion of Indigenous Australians aged 15+ who were employed in health-related occupations in 2006 ranged from 1.2% in Northern Territory to 2.4% in Victoria (Table 3.12.4).
- The proportion of Indigenous people in the health workforce was below the proportion of the population who were Indigenous in all states and territories.

Time series analyses

Tables 3.12.5, 3.12.6 and 3.12.7 show the proportion of the Australian health workforce who were Aboriginal or Torres Strait Islander by health-related occupation for the 2006, 2001 and 1996 censuses.

- In 2006 there were approximately 5,536 Indigenous Australians employed in health-related occupations, representing 1.0% of the total health workforce. Of these, the largest numbers of Indigenous Australians (1,233) were employed as midwifery and nursing professionals representing 0.6% of the nursing and midwife workforce. This was followed by Aboriginal and Torres Strait Islander health workers (965), representing 96% of Aboriginal and Torres Strait Islanders health workers (similar to 1996 and 2001).
- In 2006, Indigenous Australians represented 11.2% of health promotion officers. Health promotion officer is a new health related occupation category introduced in 2006 (Table 3.12.5).
- In 2001, there were approximately 3,998 Indigenous Australians employed in health-related occupations, representing 0.9% of the total health workforce. The highest proportion of Indigenous health workers were employed as Aboriginal and Torres Strait Islander Health Workers (93.2%) (Table 3.12.6).
- In 1996, there were approximately 3,371 Indigenous Australians employed in health-related occupations, representing 0.8% of the total health workforce. Of these the largest number of Indigenous Australians were employed as Aboriginal and Torres Strait Islander Health Workers (669 persons) representing 94.9% of all Aboriginal and Torres Strait Islander health workers. This was significantly greater than all other occupations, such that environmental health officers had the second largest proportion of Indigenous workers, but only represented 2.4% of all environmental health officers (Table 3.12.7).
- Between 1996 and 2006 there was a drop in the proportion of Indigenous health workers in the 25–34 and 35–44 age groups, and an increase in the proportion in the 45–54 and 55–64 age groups (Table 3.12.8). A similar pattern can be observed for the total health workforce (Table 3.12.9).

Additional information

Indigenous doctors

- In 2009, there were an estimated 82,895 medical practitioners working in medicine in Australia (AIHW 2011a). The number of registered practitioners increased by 22.1% between 2005 and 2009.
- According to the Australian Indigenous Doctors' Association, there are currently an estimated 153 Indigenous doctors in Australia (AIDA 2011). This represents only about 0.2% of the medical profession—well below the proportion (2.5%) of the Australia population that is Indigenous. In 2009 there were 218 Indigenous medical students: this represents 0.9% of all medical students (AIDA 2011).

Indigenous nurses

- In 2009, there were an estimated 320,982 employed nurses, 1605 (0.6%) of whom identified themselves as Aboriginal or Torres Strait Islander Australians (AIHW 2011b).
- The number of registered and enrolled nurses in the labour force (that is, employed in or looking for work in nursing in Australia) increased by 14.2% between 2005 and 2009, from 254,956 to 291,246.

Health workforce in rural and regional Australia

A report by the Department of Health and Ageing on an audit of the health workforce in rural and regional Australia in 2008 found that:

- The supply of the medical workforce—when considered as the number of doctors in comparison to the population of the area in which those doctors practise—is low to very poor in many rural and regional areas of Australia.
- The nursing workforce—when considered as a ratio of nurses to population—is relatively evenly distributed throughout rural and regional Australia.
- The supply of other health professions—particularly dental practitioners—as a ratio of professional to population, is low to poor.
- The Aboriginal health workforce is relatively small—predominantly working in *Outer regional, Remote* and *Very remote* locations.
- The supply of medical and nursing professionals varies considerably across jurisdictions. The Northern Territory, Western Australia, and the Australian Capital Territory, have lower proportions of GPs in the population and Queensland and New South Wales have the lowest proportion of nurses.
- The supply and the distribution of health professionals—in particular throughout rural and regional areas—largely correspond with the distribution of state and territory-funded health services across Australia (DoHA 2008).

Aboriginal and Torres Strait Islander primary health-care services

In 2009–10, a total of 335 full-time equivalent (FTE) doctors were employed by Indigenous primary health-care services.

Of the 335 FTE doctors employed, 25% were located in *Very remote* areas, 22% in *Outer regional* areas, 20% in *Major cities,* 19% in *Inner regional* areas and 14% in *Remote* areas. As at 30 June 2010, more than half (57% or 2,745 FTE) positions paid for by Aboriginal and Torres

Strait Islander primary health care services, were occupied by Aboriginal and Torres Strait Islander people, while 2,090 FTE staff (43%) were non-Indigenous. These proportions were similar to the previous year.

- The majority of doctors, nurses, allied health professionals and dentists employed by Indigenous primary health-care services were non-Indigenous. Most traditional healers, Aboriginal and Torres Strait Islanders health workers, sexual health workers, Bringing them Home counsellors, environmental health workers, substance use workers and drivers/field officers were Indigenous Australians (OATSIH & NACCHO 2009).
- In 2007–08, there were a small number of FTE health staff positions in Indigenous primary health-care services that were not funded by the service. These positions may be funded by state/territory health departments or through programs such as More Allied Health Services (MAHS) Program and Community Development Employment Projects (CDEP). A very small proportion of the FTE Indigenous health worker positions were held by non-Indigenous staff, and a very small proportion of FTE medical specialist/allied health professional, doctor and nurse positions were held by Indigenous staff (OATSIH & NACCHO 2009).

Data quality issues

Census of Population and Housing

The Census uses the *National health data dictionary* standard Indigenous status question and it is asked for each household member. Measures that are drawn from Census data are subject to broad data concerns relating to the unexplained growth in the Aboriginal and Torres Strait Islander population since the 1991 Census, and the limitations of self-identification. Other Census data issues relate to the accuracy of the Census count itself; for example, whether people are counted more than once, or are undercounted (ABS 1996).

Although the Census data are adjusted for undercounts at the person level to arrive at the estimated resident population, no such adjustment is done at the household level. This affects the accuracy of the person counts at the household level to provide adjusted household estimates.

List of tables

3.13 Competent governance

Measures of competent governance in mainstream and Indigenous-specific health services, including management of service delivery, compliance and accountability of services, and cultural responsiveness of service delivery for Indigenous clients

Data sources

Data related to competent governance come from the Office of the Registrar of Indigenous Corporations (ORIC), the OATSIH Services Reporting (OSR) data collection, the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS), the 2008 National Aboriginal and Torres Strait Islander Social Survey (NATSISS), and the Healthy for Life (HfL) data collection.

Office of the Registrar of Indigenous Corporations (ORIC)

The ORIC is set up to help administer the *Corporations (Aboriginal and Torres Strait Islander) Act 2006* (CATSI Act) and to support and regulate corporations for Indigenous people throughout Australia. The ORIC collects data from Indigenous corporations registered under the CATSI Act, including the number of corporations, compliance status and deregistration of corporations.

The CATSI Act replaced previous legislation, the *Aboriginal Councils and Associations Act 1976* (ACA), on 1 July 2007 (ORIC 2010).

In 2010–11, compliance analysis was able to be completed for 86 companies incorporated under the CATSI Act and registered with ORIC.

The Registrar's office supports and regulates the corporations that are incorporated under the Act. It does this in a variety of ways: by advising them on how to incorporate; by training directors, members and key staff in good corporate governance; by making sure they comply with the law; and by intervening when needed.

OATSIH Services Reporting data collection (OSR)

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in

earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of social issues including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including family and culture, health, education, employment, income, financial stress, housing, and law and justice.

Healthy for Life program

The Healthy for Life (HfL) program is an ongoing program funded by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) of the Australian Government Department of Health and Ageing (DoHA). The program aims to improve the capacity and performance of primary health-care services to deliver high-quality maternal, children's and chronic disease care to Aboriginal and Torres Strait Islander people. This is carried out through population health approaches using best-practice and quality improvement principles.

Services participating in the HfL program are required to submit de-identified, aggregate service data for 11 essential indicators. These indicators cover maternal health, child health and chronic disease care on a regular basis (6 and 12 months), as well as information about the characteristics of their service and organisational infrastructure.

The Commonwealth and the AIHW are working with the States and Territories to develop a national Key Performance Indicator (KPI) framework for Indigenous primary health care services. The new National KPIs will replace the *Healthy for Life* program Essential Indicators and cover maternal and child health and chronic disease management. The AIHW is leading the development and refinement of the indicators, data standards and analyses and reporting back to services. The national KPI data collection will be implemented in three stages, with rollout in 2012 and 2013.

Analyses

Office of the Registrar of Indigenous Corporations data

All corporations incorporated under the CATSI Act are required to submit certain documents to ORIC, including a list of members and financial reports.

- In 2010–11, compliance analysis was able to be completed for 86 companies incorporated under the CATSI Act and registered with ORIC. Of these 82, 95% were found to be compliant with providing these key documents (Table 3.13.1).
- Over the period 2000–01 to 2008–09, the proportion of Indigenous health corporations incorporated under the ACA or CATSI Act registered with ORIC that were fully or partially compliant with providing the key documents required remained between 94 and 99% (Table 3.13.2).

Table 3.13.1: Number and proportion of health corporations incorporated under the CATSI Act 2006 by compliance, 2010–11

	Number	Proportion
Compliant	82	95.3
Not compliant	4	4.7
Total	**86**	**100.0**

OATSIH Service Reporting (OSR) data

Indigenous primary health care services

- In 2010–11, there were approximately 5,731 full-time equivalent (FTE) staff employed in Indigenous primary health-care services, 3,875 (68%) health staff and 1,856 (32%) administration and support staff. The majority of both health and administration staff were Indigenous (51% and 57%, respectively) (Table 3.13.3).
- In 2010–11, the majority of Indigenous primary health-care services had governing committees/boards that met regularly (95%), had detailed income and expenditure statements presented to them on at least two occasions (99%), consisted only of Indigenous members (74%), or received training (79%) (Table 3.13.4).
- In 2010–11, 39% of Indigenous primary health-care services had representatives on external boards (for example, hospitals); 59% participated in regional planning forums and 80% were involved in committees on health (for example, steering groups) (Table 3.13.5).

Self-reported survey data

Barriers to accessing health-service providers

The 2004–05 NATSIHS collected data on whether Indigenous Australians did not access health services when needed and the reason why.

- In 2004–05, 15% of Indigenous Australian reported that they needed to but did not visit a doctor in the previous 12 month, 8% did not visit another health professional when needed and 7% did not visit a hospital when they needed to (see table 3.14.15 in Indicator 3.14 Access to services compared with need).
- Some of the reasons people didn't access services were: 10–16% did not attend services because they disliked the service/professional, felt embarrassed or afraid, another 5–6% felt the service would be inadequate (table 3.14.15 in Indicator 3.14 Access to services compared with need).

The 2008 NATSISS collected data on whether Indigenous Australians had problems accessing health services and the type of barriers they experienced, including discrimination.

- In 2008, 30% of Indigenous Australians aged 15 years and over reported that they had experienced problems accessing health-service providers. Of those who had problems accessing services, 5% identified the barrier to access the service was that the service was not culturally appropriate (Table 3.13.7).
- Further, 27% of Indigenous Australians aged 15 years and over felt that they had been discriminated against in the past 12 months, with regards to access to health services (Table 3.13.8).
- Of these Indigenous Australians, 15% (13,102) felt that they had been discriminated against by doctors, nurses or other staff at hospitals or surgeries (Table 3.13.8).
- Of the Indigenous Australians who did not feel discriminated against in the past 12 months, 0.6% (1,381 of 237,812) avoided situations with doctors, nurses or other staff

at hospitals or surgeries and 5% (11,265 of 237,812) avoided other situations (Table 3.13.8).

Indigenous persons who experienced barriers to accessing health services, by state/territory

- The Northern Territory had the highest proportion of Indigenous Australians over the age of 15 years reporting that they had experienced problems accessing services (40%) followed by Western Australia and New South Wales. The Australian Capital Territory had the lowest proportion (22%), followed by South Australia (24%) (Table 3.13.7).
- Victoria and the Australian Capital Territory had the highest proportion of Indigenous Australians who identified the barrier to accessing health services as the service being culturally inappropriate (both 7%). The Northern Territory and Queensland had the smallest proportion of Indigenous Australians reporting cultural inappropriateness as a barrier to accessing services (4%) (Table 3.13.7).

Table 3.13.7: Barriers to access health-service providers, Indigenous persons aged 15 years and over who had problems accessing services, by state/territory, 2008

Barriers to accessing health-service providers, by remoteness

- In 2008, Indigenous Australians aged 15 years and over in remote areas were more likely than those in non-remote areas to report problems accessing health services (42% and 26%, respectively). Of those who reported problems, the most commonly identified barriers to accessing health services were distrust of services (12% in non-remote areas, 7.8% in remote areas) and the services not being culturally appropriate (8.8% in non-remote areas, 5.8% in remote areas) (Table 3.13.9).
- In 2008, the percentage of Indigenous Australians aged 15 years and over who had experienced discrimination in the previous 12 months was similar for those in non-remote (28%) and remote areas (26%). Of these, 14% of those in non-remote areas, and 17% of those in remote areas felt discriminated against by doctors, nurses, or other staff at hospitals/surgeries. Two per cent of Indigenous Australians in both non-remote and remote areas said that they avoided doctors, nurses, or other staff at hospitals/surgeries because of past discrimination (Table 3.13.10).

Barriers to accessing health-service providers, by sex

- In 2008, Indigenous females aged 15 years and over in remote areas were more likely than their male counterparts to report problems accessing health services (33% and 27%, respectively) (Table 3.13.11). Of those who reported problems, the most commonly identified barrier to accessing health services was distrust of services (3.3% each for males and 3.0% for females) and the services not being culturally appropriate (1.8% for males, 2.8% for females).
- In 2008, the percentage of Indigenous Australians aged 15 years and over who had experienced discrimination in the previous 12 months was similar for males (28%) and females (27%). Of these, 11% of males, and 18% of females felt discriminated against by doctors, nurses, or other staff at hospitals/surgeries. 1.5% males and 1.6% females said that they avoided doctors, nurses, or other staff at hospitals/surgeries due to past discrimination (Table 3.13.12).

Healthy for Life data

Information on involvement in service planning and quality improvement by services funded through the HfL program is available from the AIHW Healthy for Life data collection.

- In the reporting periods ending 30 June 2008, 30 June 2009 and 30 June 2010, the most common formal mechanism for input into planning was via meetings of reference groups or other advisory committees (90%, 84% and 85%, respectively) (Table 3.13.13).
- Over the same periods, the most common formal mechanism for dissemination of health service performance information was via verbal and/or written reports presented at meetings other than the Annual General Meeting (82%, 80% and 73%, respectively).
- Over the same periods, the most common formal mechanism for assessing client satisfaction or dissatisfaction was a complaints mechanism (90%, 78% and 89%, respectively).

Services funded through the HfL program undertook quality improvement activities. Data for these activities are available for the reporting periods ending 30 June 2008, 30 June 2009 and 30 June 2010 and these indicate that:

- The services participated in formal quality improvement processes that involved repeated cycles of 'plan–do–study–act' in maternal health (between 30 June 2008 and 30 June 2010) this ranged from 67% to 72% of services, child health (ranging from 70% to 76% of services) and chronic disease (ranging from 70% to 81% of services) (Table 3.13.14).
- Health service data were used to review quality in maternal health (ranging from 66% to 85% of services), child health (ranging from 69% to 87% of services) and chronic disease (ranging from 72% to 89% of services).
- Staff participated in the interpretation of health service data and service planning/goal setting in relation to maternal health (ranging from 75% to 81% of services), child health (ranging from 74% to 87% of services) and chronic disease (ranging from 78% to 89% of services).

Table 3.13.13: Service population involvement in service planning and feedback, reporting periods ending 30 June 2008 to 30 June 2010

Data quality issues

Office of the Registrar of Indigenous Corporations (ORIC)

In 2010–11, compliance analysis was able to be completed for 86 companies incorporated under the ACA Act and registered with ORIC.

Over the period 2000–01 to 2007–08, the proportion of Indigenous health corporations incorporated under the ACA Act registered with ORIC that were fully or partially compliant with providing the key documents required remained between 95% and 99%.

OATSIH Services Reporting (OSR) data collection

The data were collected using the OSR questionnaire, (surveying all auspice services) which combined previously separate questionnaires for primary health, substance use, and Bringing Them Home and Link up counselling services.

OATSIH sent a paper copy of the 2008–09 OSR questionnaire to each participating service and asked the service to complete the relevant sections. The participating services sent their completed OSR questionnaires directly to the AIHW.

The AIHW examined all completed questionnaires received to identify any missing data and data quality issues. Where needed, AIHW staff contacted the relevant services to follow up and obtain additional or corrected data. After manually entering the data on the data repository system, staff conducted further data quality checks.

The AIHW identified three major problems with the data quality: missing data, inappropriate data provided for the question, and divergence of data from two or more questions. The majority of 2008–09 OSR questionnaires received had one or more of these data quality issues.

Further information can be found in the data quality statement in the Aboriginal and Torres Strait Islander Health Services Report, 2008–09 (AIHW 2010).

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The 2004–05 NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially ‘as reported’ by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, hence care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared to other ABS surveys. There was also an increase in under-coverage compared to previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the 2008 NATSISS User’s guide (ABS 2010).

Healthy for Life data

For the July 2008 to June 2009 reporting period, 72 services submitted data as part of the Healthy for Life Program.

Services started submitting their data through an electronic interface (OSCAR) for the February 2008 reporting period. This has improved the quality of data submitted.

Not all of the services were able to provide data for all of the essential indicators and service profile questions. The number of services who were able to provide data varies across the qualitative and quantitative indicators.

List of tables

3.14 Access to services compared with need

Access to services by types of service compared with need (for example, primary care, hospital, dental and allied health and post-acute care and palliative care)

Data sources

Data for this measure come from Medicare data, DoHA general practice statistics, the OATSIH Services Reporting Data Collection, the National Hospital Morbidity Database, the 2004–05 National Aboriginal and Torres Strait Islander Health Survey, the 2008 National Aboriginal and Torres Strait Islander Social Survey, the National Health Workforce Data Set and AIHW health expenditure data.

Medicare Database

Medicare enrolment application forms are lodged by persons wishing to enrol with Medicare at Medicare offices in each state/territory or by mail. Information from these forms is entered directly into the Medicare database, which is held by the Department of Health and Ageing (DoHA).

In November 2002, the ABS standard question on Indigenous identification was included on this form. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete.

As at 1 May 2012, 339,310 Indigenous Australians were enrolled on the VII database. This represents 59% of the estimated total Indigenous population (AHMAC 2012).

Medicare data presented in this report have been adjusted for under-identification. There are a number of caveats to the VII adjustment methodology, including that as the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could therefore be biases in the data that are not addressed by the adjustment methodology.

DoHA general practice statistics

The Commonwealth Department of Health and Ageing holds data on the number of GPs in Australia by remoteness area and Statistical Local Area (SLA). As part of the Health and Ageing 2009–10 Budget Measure- Confronting the Rural Health Challenge the Government announced that from 1 July 2009, the Rural, Remote and Metropolitan Areas (RRMA) system was replaced by the Australian Standard Geographical Classification – Remoteness Areas (ASGC-RA) system.

OATSIH Services Reporting Data Collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for 'separations' and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

National Aboriginal and Torres Strait Islander Social Survey

The Australian Bureau of Statistics (ABS) conducted the 2002 National Aboriginal and Torres Strait Islander Social Survey (NATSISS) between August 2002 and April 2003. The 2008 NATSISS was conducted between August 2008 and April 2009. The survey provides information about the Aboriginal and Torres Strait Islander populations of Australia for a wide range of areas of social concern including health, education, culture and labour force participation. The 2008 NATSISS included for the first time children aged under 15. The NATSISS will be conducted every six years, with the next survey planned for 2014.

The 2008 NATSISS collected information by personal interview from 13,300 Indigenous Australians across all states and territories of Australia, including those living in remote areas. The sample covered persons aged 15 years and over who are usual residents in selected private dwellings. It collected information on a wide range of subjects including

family and culture, health, education, employment, income, financial stress, housing, and law and justice.

National Health Workforce Data Set: medical practitioners

The AIHW, in collaboration with Health Workforce Australia, is the custodian of the National Health Workforce Data Set (NHWDS) that describes these professionals and the work they do.

The NHWDS combines data from the National Registration and Accreditation Scheme (NRAS) with health workforce survey data collected when annual registrations are renewed. The mandatory registration process is administered by the Australian Health Practitioner Regulation Agency (AHPRA) and includes an optional survey that collects additional demographic and workforce information.

All practitioners in these professions must be registered with the AHPRA to practice in Australia, and this applies whether they trained in Australia or overseas. The AHPRA manages the NRAS, which replaced jurisdiction-based registration with a single national registration and accreditation system. As part of this scheme, the AHPRA supports National Health Practitioner Boards, which regulate registered health professions under nationally consistent legislation. Registration for each profession is granted by the relevant boards, subject to applicants meeting the standards and policies set by each.

At its introduction, the NRAS covered registration for 10 health professions, with another four scheduled for inclusion from 1 July 2012 (see below). In all, this represents more than 530,000 registered health professionals.

Since 1 July 2010, these professions have been regulated: chiropractors, dental practitioners (including dentists, dental hygienists, dental prosthetists and dental therapists), medical practitioners, nurses and midwives, optometrists, osteopaths, pharmacists, physiotherapists, podiatrists, and psychologists.

From 1 July 2012, these health professions are included: Aboriginal and Torres Strait Islander health practitioners, Chinese medicine practitioners, medical radiation practitioners, and occupational therapists

Medical practitioners

The National Health Workforce Data Set (NHWDS): medical practitioners is a combination of data collected through the medical practitioner registration renewal process. Medical practitioners can either renew their registration online via the Australian Health practitioner Regulation Agency (AHPRA) website or using a paper form provided by AHPRA. For initial registration, medical practitioners must use a paper form and provide supplementary supporting documentation. Registration data collected include demographic information such as age, sex, country of birth, and details of health qualification(s) and registration status.

When medical practitioners renew their registration online, they are also asked to complete an online version of the Medical Workforce Survey 2010 questionnaire. The questionnaire collects information on the employment characteristics, work locations and work activity of medical practitioners. AHPRA stores both the online registration data and the survey information in separate databases. They then send these two data sets to AIHW, where they are merged into a de-identified national data set.

Palliative care data

Data on palliative care are sourced from the Admitted Patient Palliative Care National Minimum Data Set which is a component of the National Hospital Morbidity Data Collection (see hospitalisations section above). This is the most developed data collection currently available for reporting on palliative care services.

Palliative care in the admitted patient setting may be provided in a hospice, in a dedicated palliative care ward or other wards within a hospital.

Health Expenditure Data

The AIHW reports biennially on expenditure on health for Aboriginal and Torres Strait Islander people. The latest report in the series, *Expenditure on health for Aboriginal and Torres Strait Islander people 2008–09*, was released in 2011.

The AIHW draws upon both expenditure data and service use data to prepare Indigenous health expenditure estimates. The total expenditure and revenue data used to generate the tables are mainly administrative by-products of the accounting process, and are, as much as possible, produced on an accrual basis. Service use data, where available, provide demographic information about who is actually using the services provided.

Information obtained from Medicare Voluntary Indigenous Identifier (VII) data have been used to estimate MBS and PBS expenditure for Aboriginal and Torres Strait Islander people. The source of data used to estimate health expenditure for Indigenous and non-Indigenous Australians through Aboriginal Community Controlled Health Organisations (ACCHOs) comes from the OATSIH Service Report database.

Analyses

Age-standardised rates and ratios have been used to measure health care access in the Indigenous population relative to other Australians. Age-standardisation takes into account differences in age distributions between populations.

MBS Analysis: MBS services claimed

- In 2010-11, Medicare claims for Indigenous Australians were 5.8 million and for non-Indigenous Australians were 313 million. This was a slight increase from 2009-10 in which Medicare claims by Indigenous Australians were 5.4 million and for non-Indigenous Australians were 303 million. (Table 3.14.1).
- During 2010-11 a similar rate of service claims were made by Indigenous (14,275 per 1,000 population) and non-Indigenous (13,804 per 1,000) Australians. The largest number of claims for both Indigenous and non-Indigenous Australians were made for non-referred GP (6,376 and 5,462 per 1,000 population respectively) (Table 3.14.1).
- In 2010–11 there was an 8% difference between fees charged and benefits paid for all MBS services claimed among Indigenous Australians. This compares to a 22% difference for non-Indigenous Australians (Table 3.14.2).
- The largest difference between fees charged and benefits paid, during the same period, for both Indigenous and non-Indigenous Australians was for specialist's claims where the difference between fees charged and benefits paid was 33% for Indigenous Australians and 42% for non-Indigenous Australians (Table 3.14.2).

Notes

1. Indigenous rates should be interpreted with caution due to small population numbers in some jurisdictions. This also impacts on comparisons between jurisdictions and over time. Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. The methodology for this adjustment was developed and verified by the AIHW and the Department of Health and Ageing for assessment of MBS and PBS service use and expenditure for Indigenous Australians (For an explanation of the methodology, see *Expenditure on health for Aboriginal and Torres Strait Islander people 2006–07*).
2. In/Out refers to in and out of hospital.
3. Rates are age standardised to Australian population as at 30 June 2001.

Source: Medicare Financing & Analysis Branch, Department of Health & Ageing.

MBS services by age

Data on the number of MBS services claimed, fees charged and benefits paid by age in 2010-11 are presented in Tables 3.14.3 to 3.14.10.

- During 2010-11 for all MBS services claimed the greatest number of claims among Indigenous Australians was for those aged 60-64 years (age-standardised rate of 29,154 per 1,000 population). This was the equivalent of 17.8 million in fees charged and 15.9 million in benefits paid (Table 3.14.5, Table 3.14.7, Table 3.14.9).
- Further, during the same period among non-Indigenous Australians, the greatest number of MBS claims were also made among those 65 years and over (age standardised rate of 34,144 per 1,000 population). This was equivalent to 6,621 million in fees charged and 5,364 million in benefits paid (Table 3.14.5, Table 3.14.8, Table 3.14.10).
- Within the age ranges of 15–19 years, 20-24 years, 25-29 years, 40-44 years, 45-49 years, 50-54 years, 55-59 years and 60-64 years Indigenous Australians had a greater number of MBS claims than non-Indigenous Australians, however in the remaining age groups (<5 years, 5-9 years, 10-14 years and 65 years and over), a higher number of claims were made for non-Indigenous than Indigenous Australians (Table 3.14.5, Table 3.14.6).

Notes

1. Indigenous rates should be interpreted with caution due to small population numbers in some jurisdictions. This also impacts on comparisons between jurisdictions and over time. Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. The methodology for this adjustment was developed and verified by the AIHW and the Department of Health and Ageing for assessment of MBS and PBS service use and expenditure for Indigenous Australians (For an explanation of the methodology, see Expenditure on health for Aboriginal and Torres Strait Islander people 2006–07).
2. In/Out refers to in and out of hospital.

Notes

1. Indigenous rates should be interpreted with caution due to small population numbers in some jurisdictions. This also impacts on comparisons between jurisdictions and over time. Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. The methodology for this adjustment was developed and verified by the AIHW and the Department of Health and Ageing for assessment of MBS and PBS service use and expenditure for Indigenous Australians (For an explanation of the methodology, *see Expenditure on health for Aboriginal and Torres Strait Islander people 2006–07*).
2. In/Out refers to in and out of hospital.
3. Rates are age standardised to Australian population as at 30 June 2001.

MBS services by remoteness

Data on the number of MBS services claimed, fees charged and benefits paid by remoteness in 2010-11 are presented in Tables 3.14.11 to 3.14.17.

- The total number of MBS service claims among Indigenous Australians decreased with remoteness, such that the largest number of claims per 1,000 population were within *Major Cities* (17,440 per 1,000 population) and the smallest number of claims were within *Very Remote* areas (9,648 per 1,000 population) (Table 3.14.13).
- During 2010-11 the total number of MBS claims made by Indigenous Australians in *Major Cities* (17,440 per 1,000 population) was the equivalent of 127.0 million in fees charged and 112.8 million in benefits paid. This was compared to non-Indigenous Australians (14,550 per 1,000 population) whose claims in *Major Cities* were equal to 14,973.2 million in fees charged and 11,693.4 million in benefits paid (Table 3.14.14, Table 3.14.15, Table 3.14.16 and Table 3.14.17).
- Within *Very Remote* areas the total number of MBS claims made by Indigenous Australians was 9,648 per 1,000 population, equivalent of 25.4 million in fees charged and 25.1 million in benefits paid. This was compared to non-Indigenous Australians (8,782 per 1,000 population) whose claims in *Very Remote* areas were equal to 52.3 million in fees charged and 39.5 million in benefits paid (Table 3.14.14, Table 3.14.15, Table 3.14.16 and Table 3.14.17).
- Despite that in *Remote* areas Indigenous Australians made more MBS claims (11,436 per 1,000 population) than in *Very Remote* areas (9,648 per 1,00 population) there was a smaller amount of fees charged (18.4 million) and benefits paid (17.9 million) in *Remote* areas (Table 3.14.14, Table 3.14.15, Table 3.14.16 and Table 3.14.17).

Notes

1. Indigenous rates should be interpreted with caution due to small population numbers in some jurisdictions. This also impacts on comparisons between jurisdictions and over time. Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. The methodology for this adjustment was developed and verified by the AIHW and the Department of Health and Ageing for assessment of MBS and PBS service use and expenditure for Indigenous Australians (For an explanation of the methodology, see Expenditure on health for Aboriginal and Torres Strait Islander people 2006–07).
2. In/Out refers to in and out of hospital.
3. Rates are age-standardised to Australian 2001 population.

Notes

1. Indigenous rates should be interpreted with caution due to small population numbers in some jurisdictions. This also impacts on comparisons between jurisdictions and over time. Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. The methodology for this adjustment was developed and verified by the AIHW and the Department of Health and Ageing for assessment of MBS and PBS service use and expenditure for Indigenous Australians (For an explanation of the methodology, see Expenditure on health for Aboriginal and Torres Strait Islander people 2006–07).
2. In/Out refers to in and out of hospital.

MBS services by sex

Data on the number of MBS services claimed, fees charged and benefits paid by sex in 2010-11 are presented in Tables 3.14.18 to 3.14.21.

- During 2010–11, a comparable number of MBS claims were made among Indigenous (11,390 per 1,000 population) and non-Indigenous (11,542 per 1,000 population) males. This was equal to 117 million in fees charged and 1 million in benefits paid among Indigenous males, and 8,565 million in fees charges and 6,788 million in benefits paid among non-Indigenous males (Table 3.14.18, Table 3.14.19, Table 3.14.20, Table 3.14.21).
- During the same period there was also a comparable number of MBS claims made among Indigenous (17,003 per 1,000 population) and non-Indigenous (16,048 per 1,000 population) females. This was equal to 186 million in fees charged and 170 million in benefits paid among Indigenous females, and 11,991 million in fees charged and 9,312 in benefits paid among non-Indigenous females (Table 3.14.18, Table 3.14.19, Table 3.14.20, Table 3.14.21).

MBS services by state

Data on the number of MBS services claimed, fees charged and benefits paid by state/territory in 2010-11 are presented in Tables 3.14.22 to 3.14.27.

- During 2010-11 New South Wales had the largest number of all MBS service claims made among Indigenous Australians (age standardised rate of 17,145 per 1,000 population) and non-Indigenous Australians (age standardised rate of 14,878 per 1,000 population). This was equal to 114 million in fees charged and 103 million in benefits paid among Indigenous Australians and 7,342 million in fees charged and 5,839 million in benefits paid to non-Indigenous Australians in New South Wales (Table 3.14.22, Table 3.14.23, Table 3.14.24, Table 3.14.26, Table 3.14.27).
- During 2010-11 the smallest number of all MBS service claims made among Indigenous Australians was in Western Australia (age standardised rate of 11,437 per 1,000 population). This was equal to 30 million in fees charged and 27 million in benefits paid (Table 3.14.22, Table 3.14.24, Table 3.14.26).
- During the same period, the smallest number of all MBS service claims made among non-Indigenous Australians was in the Northern Territory (age standardised rate of 8,534 per 1,000 population). This was equal to 83 million in fees charged and 60 million in benefits paid (Table 3.14.23, Table 3.14.25, Table 3.14.27).

Notes

1. Indigenous rates should be interpreted with caution due to small population numbers in some jurisdictions. This also impacts on comparisons between jurisdictions and over time. Medicare data presented by Indigenous status have been adjusted for under-identification in the Medicare Australia Voluntary Indigenous Identifier (VII) database. The methodology for this adjustment was developed and verified by the AIHW and the Department of Health and Ageing for assessment of MBS and PBS service use and expenditure for Indigenous Australians (For an explanation of the methodology, see *Expenditure on health for Aboriginal and Torres Strait Islander people 2006–07*).
2. In/Out refers to in and out of hospital.
3. Rates are age standardised to Australian population as at 30 June 2001.

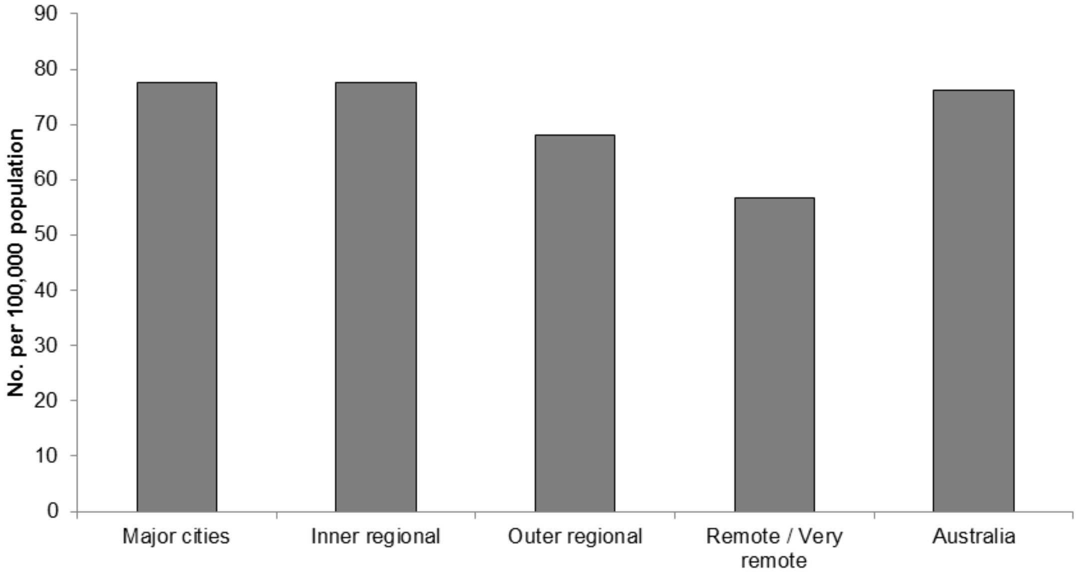
General practitioners

Information on the number of GPs working in Australia is available from DoHA. Data in Table 3.14.28 and Figure 3.14.1 present the number of full-time equivalent GPs per 100,000 population by ASGC remoteness areas.

- In 2010–11, there were 16,927 GPs registered and working in Australia. 70% of these GPs practiced in *Major cities*, where approximately 69% of the population resided. Around 291, or 1.7%, practiced in *Remote* and *Very remote* areas, where 2.3% of the Australian population resided.
- The number of GPs per 100,000 head of population was greatest in *Major cities* (78 per 100,000) and lowest in *Remote* and *Very remote* areas (57 per 100,000).



Source: DoHA 2012.

Figure 3.14.1: Number of full-time equivalent GPs per 100,000 population, by remoteness, 2010–11

Table 3.14.28: Number of FTE GPs, and number per 100,000 population, by remoteness, 2010–11

	Major cities	Inner regional	Outer regional	Remote / Very remote	Australia
Number of GPs	11,917	3,338	1,381	291	16,927
GPs per 100,000	77.7	77.5	68.1	56.7	76.3

GPs who bulk bill

No data are currently available on the number of GPs who bulk bill by remoteness area. Data on the proportion of medical services that bulk bill are available by electoral roll and state and territory. State and territory data are presented below.

- In 2009–10, approximately 80% of general practitioner attendances were bulk billed. This ranged from 47% in the Australian Capital Territory to 84% in New South Wales (Table 3.14.29).

Table 3.14.29: Proportion of medical services that bulk bill, by state/territory, 2009–10

	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	Australia
Bulk billing per cent	84.4	78.2	78.9	72.5	78.7	74.3	47.1	65.6	79.5

Aboriginal and Torres Strait Islander health services

Data on Indigenous primary health-care services are available from the OSR data collection collected by the AIHW.

Primary health-care services

Episodes of health care

Episodes of health care are defined in the OSR data collection as 'contact between an individual client and a service by one or more staff to provide health care, such as for sickness, injury, counselling, health education or screening'. Episodes of care data includes:

- health care provided to clients through all sources of funding
- outreach visits (e.g. homelands/outstation visits, park clinics and satellite clinics)
- health care provided to clients over the telephone
- visitors/transients episodes of care.

Tables 3.14.30 and 3.14.31 show the total estimated number of episodes of health care provided by respondent Indigenous primary health-care services by remoteness area in each state and territory.

- In 2010–11, the number of episodes of health care provided across each state and territory varied. The majority of the estimated episodes of health care reported were provided in *Remote* and *very remote* areas.

Table 3.14.30: Total episodes of health care provided by respondent Aboriginal and Torres Strait Islander primary health-care services, by remoteness and Indigenous status, 2010–11

	Major cities	Inner regional	Outer regional	Remote	Very remote	Total

Health staff

- At June 2011, a total of 362 FTE doctors and 789 FTE nurses were employed by Indigenous primary health-care services. The majority of doctors, nurses, allied health professionals and dentists were non-Indigenous (93%, 90%, 76% and 87%, respectively). The majority of Indigenous health workers, social and emotional wellbeing staff, traditional healers, environmental health workers, substance-use workers, sexual health workers, dental support workers and drivers/field officers were Aboriginal and Torres Strait Islander Australians (Table 3.14.32).

Table 3.14.32: Number of full-time equivalent health staff employed by respondent Aboriginal and Torres Strait Islander primary health-care services, by Indigenous status, as at 2010–11

	Aboriginal and Torres Strait Islander staff	Non-Indigenous staff	Unknown status	Total FTE
AHW[(a)] male	261.1	4.3	1.0	266.4
AHW[(a)] female	638.3	9.7	2.0	650.0
Doctors	26.0	335.4	0.2	361.6

Other health staff[(e)]	149.9	77.2	20.6	230.3

(a) AHW - Aboriginal health worker.

(b) SEWB - Social and emotional wellbeing staff, includes counsellors, social workers, psychologists.

(c) AHP - allied health professionals.

(d) EHW - environmental health workers.

(e) Other health staff - all other health related staff not included above.

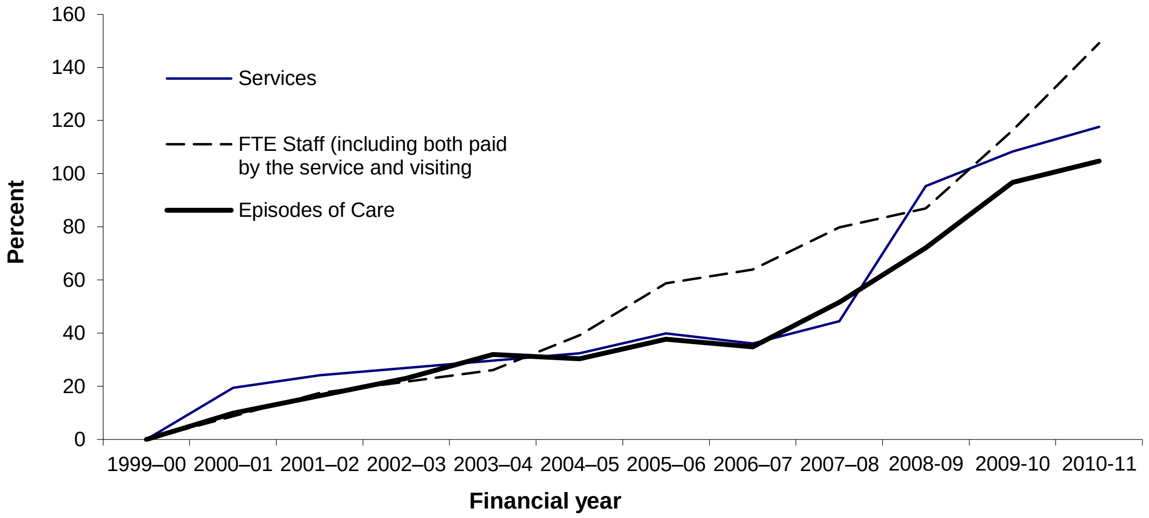
Source: AIHW OSR data collection.

Episodes of health care and health staff—time series analyses

Data presented below include those services that have been included in the SAR data collection (1999–00 to 2007–08) and OSR data collection (2008-09 to 2010-11).

- Over the period 1999–00 to 2010–11, there has been a rise of 104% in the number of Aboriginal and Torres Strait Islander primary health-care services (Figure 3.14.2; Table 3.14.33).
- Over the same period, there was a steady increase of 96% in the total number of estimated episodes of health care provided to Indigenous and non-Indigenous Australians.

- There was a 135% rise in full-time equivalent staff employed by Indigenous primary health-care services between 1999–00 and 2010–11.



Notes

1. 2008–09 OSR data counts all auspice services individually when calculating rates, therefore caution should be exercised when comparing rates with earlier data collection periods.
2. Eligible services only for 2007–08 services.

Sources: AIHW SAR and OSR data collections.

Programs/activities provided

Aboriginal and Torres Strait Islander primary health-care services offer a range of programs and activities to support their communities.

Drug and alcohol programs

- In 2010–11, 89% (209) of the 234 services that reported in the OSR provided alcohol and other drug programs (AIHW 2012a).

Further detail can be found in 3.11: Access to alcohol and drug services.

Palliative care, funeral assistance and deceased transportation

- In 2010–11, the majority (47%) of Indigenous primary health-care services reported in the OSR provided funeral assistance, although just under half (46%) provided palliative care and one in seven (14%) provided transportation for the deceased (Table 3.14.34).

Table 3.14.34: Proportion of Aboriginal and Torres Strait Islander primary health-care services providing palliative care, funeral assistance and transportation for the deceased, 2010–11

	Total number	Per cent
Palliative care	107	45.7
Funeral assistance	111	47.4
Deceased transportation	33	14.1
Total primary health care services	**234**	**100.0**

Note: All of the 234 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data about health related activities provided by the service. The percentages in the table above are calculated as a proportion of these 234 services.

Source: AIHW OSR data collection.

Hospitalisations

- In the 2-year period July 2008 to June 2010 there were a total of 13,598,800 hospitalisations for Indigenous and non-Indigenous Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Of these, 331,383 or 2.4% were hospitalisations of Indigenous Australians.

An analysis of hospitalisations, excluding those for routine dialysis, is presented in measure 1.02: Top reasons for hospitalisation.

Hospitalisations by age group

- For the period 2008–09 to 2009–10, Indigenous Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined had higher hospitalisation rates than non-Indigenous Australians across all age groups except 65 years and above (Table 3.14.35).
- The greatest difference in rates occurred in the 35–44 and 45–54 year age groups (154.2 and 174.3), where Indigenous Australians were hospitalised at almost two times the rate of non-Indigenous Australians in these age groups.

Table 3.14.35: Age-specific hospitalisation rates (excluding dialysis), by Indigenous status and age group, NSW, Vic, Qld, WA, SA and NT combined, July 2008 to June 2010[(a)(b)(c)]

	Indigenous		Non-Indigenous Australians			
Age group	Number	Number per 1,000	Number	Number per 1,000	Ratio[(d)]	Rate difference[(e)]
0–4	42,113	326.2	583,795	224.5	1.5*	101.7*
5–14	25,676	103.6	423,634	83.7	1.2*	19.9*

65+	27,255	793.7	4,708,803	844.9	0.9*	–51.3*

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Financial year reporting.

(c) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(d) Rate ratio Indigenous: non-Indigenous Australians.

(e) Rate difference Indigenous minus non-Indigenous Australians.

Notes

1. Rates for Indigenous are calculated using population estimates based on the 2006 Census (SERIES B).
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by state/territory

Table 3.14.36 presents hospitalisations for all diagnoses for the two-year period July 2008 to June 2010 for New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory.

- Over the period July 2008 to June 2010, Indigenous Australians in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined were hospitalised at 1.3 times the rate of non-Indigenous Australians.
- Indigenous Australians in Victoria were hospitalised at similar rates to non-Indigenous Australians. Indigenous Australians in New South Wales and Queensland were hospitalised at 1.2 times and 1.3 times the rate of non-Indigenous Australians. In Western Australia and South Australia, Indigenous Australians were hospitalised at 1.5 and 1.6 times the rate of non-Indigenous Australians; and in the Northern Territory, Indigenous Australians were hospitalised at 2.2 times the rate of non-Indigenous Australians (Table 3.14.36).

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Financial year reporting.

(c) Data are reported by state/territory of usual residence of the patient hospitalised.

(d) Age standardised rates for New South Wales, Victoria, Queensland, Western Australia, South Australia, the Northern Territory and Australia have been calculated using the direct method, age standardised by 5 year age groups to 75+. Age standardised rates for Tasmania and the Australian Capital Territory have been calculated using the direct method, age standardised by 5 year age group to 65+.

(e) Directly age-standardised using the Australian 2001 standard population.

(f) Rate ratio Indigenous: non-Indigenous.

(g) Rate difference Indigenous minus non-Indigenous.

(h) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(i) Includes all separations in all eight states and territories, including the Australian Capital Territory and Tasmania; Other Territories and Residence State not applicable (e.g. overseas, at sea, no fixed address).

Notes

1. Rates for Indigenous are calculated using population estimates based on the 2006 Census (SERIES B).
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Hospitalisations by remoteness

Hospitalisation rates in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory combined are presented by Australian Standard Geographical Classification (ASGC) in Table 3.14.37, covering the period July 2008 to June 2010.

- Rates of hospitalisations per 1,000 population were highest for Indigenous Australians living in *Remote* areas, at 597 per 1,000. The rate was highest for non-Indigenous Australians who lived in *inner regional* areas, at 316 per 1,000. The lowest rates were observed in *Major cities* for Indigenous Australians (319 per 1,000) and *Remote* areas for non-Indigenous Australians (292 per 1,000).
- Indigenous Australians were more likely to be hospitalised than non-Indigenous Australians across all remoteness areas. Indigenous Australians were hospitalised at twice the rate of non-Indigenous Australians in *Remote* areas of Australia. *Major cities*, had the lowest ratio (1.02). Nationally, the rate ratio was 1.3 times.

Table 3.14.37: Hospitalisations (excluding dialysis) by Indigenous status and remoteness, NSW, Vic, Qld, WA, SA and NT, July 2008 to June 2010[(a)(b)(c)(d)(e)(f)]

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification of Health 2010).

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised.

(e) Directly age-standardised using the Australian 2001 standard population, by 5 year age groups to 65+.

(f) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(g) LCL = lower confidence limit.

(h) UCL = upper confidence limit.

(i) Rate ratio Indigenous: non-Indigenous.

(j) Rate difference Indigenous- non-Indigenous.

(k) Includes remote Victoria.

(l) Excludes remote Victoria.

(m) Total includes hospitalisations where ASGC is missing.

Notes

1. Rates are calculated using the remoteness distribution by Indigenous status, age and sex based on the 2006 ERP and applied to the 2008–10 population projections (Series B) based on the 2006 Census.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

Source: AIHW analysis of National Hospital Morbidity Database.

Time series analyses

Time series data are presented for the four jurisdictions that have been assessed as having adequate identification of Indigenous hospitalisations for all years from 1998–99 to 2009–10: Queensland, Western Australia, South Australia and the Northern Territory. These four jurisdictions represent approximately 60% of the Indigenous Australian population.

Hospitalisation rates, rate ratios and rate differences between Indigenous and other Australians over the period 1998–99 to 2009–10 are presented in Table 3.14.38 and Figure 3.14.3.

- In Queensland, Western Australia, South Australia and the Northern Territory combined, there were significant increases in hospitalisation rates among Indigenous Australians during the 11-year period from 1998–99 to 2009–10. The fitted trend implies an average yearly increase in the rate of around 2.2 per 1,000 which is equivalent to a 6% increase in the rate over this period.
- There were also significant increases in hospitalisation rates among non-Indigenous Australians during the same period, with an average yearly increase in the rate of 3.0 per 1,000 for non-Indigenous Australians. This is equivalent to a 14% increase in the rate over this period.
- There were significant increases in the hospitalisation rate ratios and rate differences between Indigenous and non-Indigenous Australians. The fitted trend implies an average yearly decline of 0.01 in the rate ratio (7% decline over the period) and 1 per 1,000 in the hospitalisation rate differences between Indigenous and non-Indigenous Australians over this period (8% decline). This indicates a relative and absolute decline in the gap between hospitalisation rates for Indigenous and non-Indigenous Australians.

Note that changes in the level of accuracy of Indigenous identification in hospital records will result in changes in the level of reported hospital separations for Indigenous Australians. Also, changes in access, hospital policies and practices all have an impact on the level of hospitalisation over time. Caution should be used in interpreting changes over time because it is not possible to ascertain whether a change in reported hospitalisation is due to changes in the accuracy of Indigenous identification or real changes in the rate at which Indigenous Australians are hospitalised. An increase in hospitalisation rates may also reflect better access to hospitals, rather than a worsening of health.

Table 3.14.38: Age-standardised hospitalisation rates, rate ratios and rate differences (excluding dialysis), Qld, WA, SA and NT, 1998–99 to 2009–10[(a)]

Source: AIHW analysis of National Hospital Morbidity Database.

Figure 3.14.3: Hospitalisation rates, rate ratios and rate differences between Indigenous and non-Indigenous Australians (excluding dialysis), Qld, WA, SA and NT combined, 1998–99 to 2009–10

Hospitalisations for palliative care data

Data on palliative care are sourced from the Admitted Patient Palliative Care National Minimum Data Set, which is a component of the National Hospital Morbidity Data Collection.

Information on hospitalisations for palliative care is presented in Table 3.14.39 and 3.14.40.

Hospitalisations for the two-year period July 2008 to June 2010 are presented for New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Over this period, Indigenous Australians in these jurisdictions combined were hospitalised for palliative care at around 1.6 times the rate of non-Indigenous Australians.

- Over the period July 2008 to June 2010, Indigenous Australians in Victoria, Queensland and Western Australia were hospitalised for palliative care at about twice the rate of non-Indigenous Australians. In Queensland, Indigenous females were hospitalised for palliative care at higher rates than non-Indigenous females. In the Northern Territory, Indigenous Australians were hospitalised for palliative care at lower rates than non-Indigenous Australians. The number of hospitalisations for palliative care for Indigenous Australians in most jurisdictions was very small and thus the rates should be interpreted with caution (Table 3.14.39).

Hospitalisation rates for palliative care in New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory are presented by Australian Standard Geographical Classification (ASGC) in Table 3.06.52, covering the period July 2008 to June 2010. Due to the small numbers of hospitalisations of Indigenous Australians recorded in theses jurisdictions, caution should be exercised when interpreting these rates.

- Indigenous Australians in all ASGC areas were more likely to be hospitalised for palliative care than non-Indigenous Australians. The ratio of hospitalisations of Indigenous Australians compared with non-Indigenous Australians was higher and the difference was statistically significant for all ASGC areas except for *very remote* areas.
- Rates of hospitalisations for palliative care per 1,000 populations were highest for Indigenous Australians living in *Major cities*, *Inner regional* and *Outer regional* areas, at 2.1 per 1,000. The rate was highest for non-Indigenous Australians who lived in *Major cities*, at 0.6 per 1,000. The lowest rates of hospitalisations for palliative care per 1,000 population were observed in *Very remote* areas for Indigenous Australians (1.0 per 1,000) and *Remote* areas for other Australians (0.8 per 1,000).
- Indigenous Australians were hospitalised for palliative care at a rate of 2.4 times that of non-Indigenous Australians in *Remote* areas of Australia. In *Very remote* areas, where the lowest ratio was observed, Indigenous Australians were hospitalised at 1.2 times the rate to that of non-Indigenous Australians. For all ASGC areas combined, the rate ratio was 1.5.

Persons	n.p.	n.p.	1,051	1.7	n.p.	n.p.

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the p < 0.05 level.

(a) Data are from public and most private hospitals. Jurisdictional data excludes private hospitals in the Northern Territory, Tasmania and the Australian Capital Territory.

(b) Financial year reporting.

(c) Data are reported by state/territory of usual residence of the patient hospitalised.

(d) Age standardised rates for New South Wales, Victoria, Queensland, Western Australia, South Australia, the Northern Territory and Australia have been calculated using the direct method, age standardised by 5 year age groups to 75+. Age standardised rates for Tasmania and the Australian Capital Territory have been calculated using the direct method, age standardised by 5 year age group to 65+.

(e) Directly age-standardised using the Australian 2001 standard population.

(f) Rate ratio Indigenous: non-Indigenous.

(g) Rate difference Indigenous minus non-Indigenous.

(h) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

Notes

1. Rates for Indigenous are calculated using population estimates based on the 2006 Census (SERIES B).
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.
3. n.p. indicates not available for publication, due to small numbers (less than 5) but included in totals where applicable.

* Represents results with statistically significant differences in the Indigenous/non-Indigenous comparisons at the $p < 0.05$ level.

(a) Data are from public and most private hospitals. Data exclude private hospitals in the Northern Territory, the Australian Capital Territory and Tasmania.

(b) Categories are based on the ICD–10–AM sixth edition (National Centre for Classification of Health 2010).

(c) Financial year reporting.

(d) Data are reported by state/territory of usual residence of the patient hospitalised.

(e) Age standardised rates for New South Wales, Victoria, Queensland, Western Australia, South Australia, the Northern Territory and Australia have been calculated using the direct method, age standardised by five year age group to 65+.

(f) New South Wales, Victoria, Western Australia, South Australia, the Northern Territory and Queensland are considered to have adequate levels of Indigenous identification, although the level of accuracy varies by jurisdiction and hospital. Hospitalisation data for these six jurisdictions should not be assumed to represent the hospitalisation experience in the other jurisdictions.

(g) Directly age-standardised using the Australian 2001 standard population, by 5 year age groups to 65+.

(h) LCL = lower confidence limit.

(i) UCL = upper confidence limit.

(j) Rate ratio Indigenous: non-Indigenous Australians.

(k) Rate difference Indigenous minus non-Indigenous.

(l) Includes remote Victoria.

(m) Excludes remote Victoria.

(n) Total includes hospitalisations where ASGC is missing.

Notes

1. Rates are calculated using the remoteness distribution by Indigenous status, age and sex based on the 2006 ERP and applied to the 2008–10 population projections (Series B) based on the 2006 Census.
2. Care types 7.3, 9 & 10 (Newborn – unqualified days only; organ procurement; hospital boarder) excluded from analysis.

National Aboriginal and Torres Strait Islander Health Survey—access to health care

The 2004–05 NATSIHS collected information on Indigenous Australians' access to health services. These data are presented in Tables 3.14.41–3.14.48.

- In 2004–05, approximately 42% of Indigenous Australians had accessed health care in the last 12 months (Table 3.14.41).
- After adjusting for differences in age structure, approximately 47% of Indigenous Australians reported they had accessed health care in the last two weeks or were admitted to hospital in the last 12 months, compared with 42% of non-Indigenous Australians.
- Approximately 25% of Indigenous Australians reported they had visited a doctor or specialist in the last two weeks, 20% had been admitted to hospital in the last 12 months and 20% had consulted with other health professionals in the last two weeks.
- Indigenous Australians were twice as likely to have visited casualty or consulted with another health professional than non-Indigenous Australians.
- Indigenous and non-Indigenous Australians aged 55 years and over were most likely to have accessed health care in the last two weeks (66% and 57%, respectively) (Table 3.14.41).
- A higher proportion of Indigenous Australians aged 15 years and over with reported fair/poor health status accessed health care in the last 12 months than Indigenous Australians with excellent/very good or good health status (64% compared with 44%) (Table 3.14.42).
- Indigenous Australians aged 15 years and over with fair/poor health status were twice as likely to have visited casualty in the last 12 months than non-Indigenous Australians.
- Approximately 60% of Indigenous Australians and 56% of non-Indigenous Australians with three or more long-term health conditions reported they accessed health care in the last 12 months (Table 3.14.43).
- In 2004–05, a higher proportion of Indigenous females had accessed health care in the last two weeks (45%) than Indigenous males (38%) (Table 3.14.44).
- In 2004–05, approximately 42% of Indigenous Australians reported they had accessed some type of health care in the last two weeks. The proportion who had accessed health care ranged from 35% in the Australian Capital Territory to 52% in the Northern Territory (Table 3.14.45).
- Indigenous Australians living in *Very remote* areas of Australia were more likely to have accessed health services than Indigenous Australians in *Major cities* (55% compared with 44%) (Table 3.14.46).
- In non-remote areas of Australia, Indigenous Australians accessed health care at similar rates to non-Indigenous Australians (46% compared with 43%) (Table 3.14.47).
- Between 2001 and 2004–05, there was little change in the proportion of Indigenous and non-Indigenous Australians accessing health care (Table 3.14.48).

Access to health care by selected population characteristics

- In 2004–05, Indigenous Australians were more likely to have accessed health care by visiting casualty/outpatients than the non-Indigenous Australians (Table 3.14.49).

- Indigenous Australians in the lowest quintile of equivalent household income were six times more likely to have accessed health care by visiting casualty/outpatients than the non-Indigenous Australians those in the lowest quintile (Table 3.14.49).
- Indigenous Australians who completed year 12 were more likely to have accessed health care than non-Indigenous Australians who had completed year 12.
- In 2004–05, Indigenous Australians who are employed accessed health services by visiting casualty/outpatients at approximately seven times the rate of non-Indigenous Australians who are employed (Table 3.14.49).

Time since last consulted a doctor or dentist

- In 2004–05, after adjusting for differences in age structure, approximately 36% of Indigenous Australians reported that it had been two years or more since their last dental consultation. This compared with 29% of non-Indigenous Australians (Table 3.14.50).
- Approximately 25% of Indigenous Australians reported it had been two weeks or less since their last visit to a doctor (GP or specialist) compared with 23% of non-Indigenous Australians, and for 26% of Indigenous Australians it had been two weeks to three months since their last doctor consultation compared with 28% of non-Indigenous Australians.
- There was little change in the time since last doctor consultation for Indigenous and non-Indigenous Australians between 2001 and 2004–05. For dental visits, there was a reduction in the two years or more categories over this time period.

Indigenous Australians who did not access health care when needed and why

Table 3.14.51 presents data on whether Indigenous Australians needed to access a dentist, doctor, other health professional or hospital in the last 12 months, but didn't, and the reasons why they didn't access these health services.

- In 2004–05, approximately 21% of Indigenous Australians reported they needed to go to a dentist in the last 12 months, but didn't, 15% needed to go to a doctor, 8% needed to go to another health professional and 7% needed to go to hospital, but didn't.
- Indigenous Australians in non-remote areas were more likely to report that they needed to access a dentist, doctor or other health professional, but didn't, than Indigenous Australians in remote areas.
- Indigenous females were more likely to report they needed to go to a dentist or doctor, but didn't (23% and 17%, respectively) compared with Indigenous males (19% and 13%, respectively).
- Indigenous Australians aged 15–44 and 45 years and over were more likely to report they needed access to these services, but didn't go, than Indigenous Australians aged 0–14 years.
- The most common reasons why Indigenous Australians did not go to a dentist when needed were cost (29%), waiting time was too long or not available at the time required (22%) and feeling afraid, embarrassed or a dislike of the service (21%).
- The most common reasons why Indigenous Australians did not go to a doctor when needed were that they decided not to seek care (26%), too busy (24%), transport/distance difficulties (14%) and waiting time too long or not available at time required (14%).
- The most common reasons why Indigenous Australians did not go to another health professional when needed was cost (28%) and too busy (26%).
- The most common reasons why Indigenous Australians did not visit a hospital when needed was that they decided not to seek care for their health problem (25%) and transport/distance issues (19%).
- A higher proportion of Indigenous Australians living in remote areas reported transport/ distance as a reason for not accessing health services than Indigenous Australians in non-remote areas.

Co-payment and private health insurance

Information on co-payment and private health insurance was collected in non-remote areas of Australia only, and is presented in Tables 3.14.52 and 3.14.53.

- In 2004–05, approximately 15% of Indigenous Australians in non-remote areas required co-payment for their last visit to the doctor, 37% required co-payment for their last visit to a specialist and 17% required co-payment for their last visit to other health professionals (Table 3.14.52).
- In 2004–05, a much higher proportion of Indigenous Australians in non-remote areas reported they were not currently covered by private health insurance than non-Indigenous Australians (83% compared with 49%) (Table 3.14.53).
- The most common reasons for why Indigenous Australians had private health insurance were security, protection or peace of mind (43%), a shorter wait for treatment or concern over public hospital waiting lists (20%), and provision of benefits for ancillary services or extras (18%). Similar proportions of non-Indigenous Australians reported these reasons for also having private health insurance.
- The most common reasons for Indigenous Australians not having private health insurance were that they could not afford it (65%), and that they felt that Medicare cover was sufficient (19%).

Treatment when seeking health care

- In 2004–05, about 4% of Indigenous people reported that when they sought health care in the last 12 months they were treated worse than non-Indigenous people, 77% reported they were treated the same as non-Indigenous people, and 5% reported they were treated better than non-Indigenous people (Table 3.14.54).
- A higher proportion of Indigenous people in remote areas reported they were treated better than non-Indigenous people (11% compared with 3%).
- Approximately 16% of Indigenous people felt that they were treated badly when they sought health care because they were Indigenous.
- The most common feeling felt when Indigenous people thought they had been treated badly when seeking health care was anger (67%). Approximately 31% of Indigenous people reported they felt sorry for the persons who had treated them badly and 28% of Indigenous people felt sad as a result of being treated badly.
- Approximately 38% of Indigenous people who reported being treated badly when seeking health care reported that they talked to friends or family about the situation, 33% reported they try to avoid the situation or person involved and 30% try to do something about the people involved.

National Aboriginal and Torres Strait Islander Social Survey data

Data from the 2008 NATSISS is presented in Tables 3.14.55 to 3.14.59.

Problems accessing health services

- The 2008 NATSISS showed that 26% of Indigenous Australians aged 15 years and over had problems accessing health services (Table 3.14.55).
- Indigenous Australians aged 15 years and over in remote areas had a higher proportion of having problems accessing health services than those in non-remote areas (36% compared to 23%).
- Around 52% of Indigenous Australians aged 15 years and over who had problems accessing health services were because that waiting time was too long or service was not available at time required. 42% were because not enough services in the area and 34% were because transport/distance.
- Nationally, around 20% Indigenous Australians aged 15 years and over had problems accessing dentists and 10% had problems accessing doctors. In remote areas, the proportions of having problems accessing dentists and doctors were 27% and 12% respectively.

Problems accessing services

- In 2008, 30% of Indigenous Australians aged 15 years and over reported they had a problem accessing services. The greatest problem was with accessing dentists (20% reported problems accessing), followed by accessing doctors (10%). The greatest barriers to accessing services were that the waiting time was too long or that the service was not available at the time required (15%).
- Table 3.14.56 shows that the Indigenous Australians in the Northern Territory (40%) had the highest rate of problems accessing services. The rate was lowest in South Australia (24%).
- Table 3.14.57 reports data on problems accessing services for Indigenous Australians aged 15 years and over by the remote and non-remote categories. Respondents in remote areas had greater problems accessing services (42%) than their non-remote counterparts (26%), and reported greater problems accessing every type of service identified in the table, except for other services. The largest disparities regarding the barriers to accessing these services was with 'no services in the area', 'not enough services in the area' or 'transport/distance'.
- A difference was also evident when problems accessing services for Indigenous males aged 15 years and over was compared with their female counterparts. One third (33%) of females reported they had problems accessing services, compared with 27% of males (Table 3.14.58).
- Of Indigenous Australians aged 15 years and over, the age group with the greatest percentage reporting problems accessing services was those aged 35–44 years (35%), while the lowest was for 15–24 year olds (23%) (Table 3.14.59).

Barriers to accessing services

Aboriginal and Torres Strait Islander people face a number of barriers to accessing services, including lack of transport (particularly in remote areas), financial difficulties and proximity of culturally appropriate services. The proportion of Aboriginal and Torres Strait Islander people involved in health-related professions can also affect use of health services by Indigenous Australians.

See measure 3.12: Aboriginal and Torres Strait Islander people in the health workforce for further information.

Transport

Although distance to various health services provides one measure of access, lack of transport can often mean that comparatively short distances are an impediment to service use. Data are available from the 2006 Census and the 2008 NATSISS on access to motor vehicles and difficulties with transport.

- In 2006, households with Indigenous Australians were less likely than non-Indigenous households to have at least one motor vehicle. Approximately 78% of Indigenous and 86% of non-Indigenous households had at least one motor vehicle.
- In 2008, Indigenous Australians in every state and territory, apart from Tasmania, were less likely to report having access to a motor vehicle(s) than other Australians. The Northern Territory had the lowest proportion of Indigenous households with access to at least one motor vehicle (68%) and Tasmania had the highest proportion (89%) (see Table 2.13.9).
- In 2008, around 11% of Indigenous Australians reported that they could not get, or often had difficulty getting, to places needed, compared with only 4.2% of other Australians (Table 3.14.60).

Source: 2008 NATSISS and 2006 GSS.

The data on vehicles per household and per person suggest that other Australians have better access to personal transport than Indigenous Australians and would therefore be more readily able to reach a health facility or service. Public transportation may compensate for the lack of personal transport, and some clinics may provide a transport service for their patients, but this service are not available everywhere.

For more information on transport see measure 2.13: Transport.

Affordability

Data on the financial stress of Indigenous Australians were collected in the 2008 NATSISS.

- In 2008, about half (46%) of all Indigenous Australians aged 15 years and over reported they were living in households in which they could not raise $2,000 within a week in a time of crisis.
- Indigenous Australians living in remote areas of Australia were more likely to have financial difficulties, with 51% unable to raise $2,000 compared with 31% in non-remote areas.

This information suggests that many Indigenous Australians suffer financial difficulties of some kind, especially those living in remote areas of Australia. Financial difficulties are an important barrier to accessing services where costs are involved.

Many privately provided health services involve direct out-of-pocket payments by patients. These have a greater impact on people with limited economic means and, given the generally poorer economic position of Aboriginal and Torres Strait Islander people, the effect is likely to be greater on them than on other Australians. Examples of this are services provided by dentists, physiotherapists and other health professionals that are not covered by Medicare, and pharmaceuticals that are not covered by the Pharmaceutical Benefits Scheme (PBS). These do not attract subsidies from governments and, therefore, patients meet out-of-pocket fees when these services are accessed. Other services, such as medical services covered by Medicare and pharmaceuticals covered by the PBS, although subsidised, can also involve out-of-pocket expenditure, which restrict the access of people in lower socioeconomic groups.

Medical services subsidised under Medicare can attract copayments if they are not bulk-billed. In the June quarter 2012, 76% of GP attendances were bulk-billed (DoHA 2012). Patients who are not bulk billed are usually required to pay the full fee at the time of service and can then seek a refund from Medicare. This, however, means that they must first be able to pay for the service. This difficulty is further exacerbated by the fact that some practitioners charge fees above the Medicare Benefits Schedule fee, requiring larger gap payments, which are generally borne by the patients. Medicare benefits are payable for services provided by Aboriginal Community Controlled Health Services and patients of these services are bulk billed.

People who are prescribed pharmaceuticals under the PBS are also required to make out-of-pocket copayments. The amount that a patient needs to find is adjusted to some extent in accordance with the patient’s ability to pay. Different copayments apply to concession card holders, pensioners and general patients. The PBS also has safety net provisions that protect individuals and families from large overall expenses for PBS medicines.

Telephone and Internet use

Access to a working telephone in the home is often considered a necessity in cases of emergency so that health services, such as hospitals, ambulances and doctors, can be contacted quickly. People without a working telephone in the home are less equipped to seek medical help when required. Internet access is becoming an increasingly important vector of communication, and a means of transacting with government and non-government agencies, as well as being a source of information and opinion.

The 2008 NATSISS collected information on whether Indigenous Australians had access to the internet in their household, as well as data on the types of telephones used by household members in the past month.

- In 2008, 98% of households had a member who had used a telephone in the last month. The most common types of telephone used in the past month were pre-paid mobile phones and landlines in the home (68% and 67%), followed by contract mobiles (39%). Landlines in neighbours houses and other phones were the least likely to have been used (6.1% and 1.3%).
- That same year, 62% of households had at least one computer in working order. Of those households with a working computer, 77% also had an internet connection.

Health labour force

Information on the health labour force is available from the National Health Workforce Data Set (NHWDS) and the AIHW Nursing and midwifery labour force survey.

Clinical medical practitioners

- In 2010, there were 52,497 medical practitioners employed in medicine in Australia. Most employed medical practitioners in Australia in 2010 were working as clinicians (93.6%). The rate of FTE employed clinical medical practitioners in Australia was 345 per 100,000. Clinical medical practitioners are comprised of primary care practitioners (35%), specialists (36%), specialists-in-training (16%) and hospital non-specialists (10%) (Table 3.14.61; Figure 3.14.6; AIHW 2012b).
- The greatest regional disparity among clinicians was observed among specialists, where there were four times the rate of specialists present in Major cities than in Remote and Very remote areas (147 and 40 per 100,000, respectively). Major cities had double the rate of specialists as Inner regional areas (75 per 100,000).

Table 3.14.61: Full time employed medical practitioners by main occupation and geographic region of main job, 2010[(a)]

Main occupation	Region of main job Major cities	Inner regional	Outer regional	Remote / Very remote[(b)]	Australia[(c)]
	Full-time equivalent rate per 100,000 population

Nurses and midwives

This section presents information on nurses and midwives in Australia based on data from the 2009 AIHW Nursing and Midwifery Labour Force Survey. This survey collected information on the demographic and employment characteristics of nurses who were registered or enrolled in Australia at the time of the survey. The survey was done annually until 2009 by state and territory health authorities, with the questionnaire administered by the registration boards (or councils) in each jurisdiction, usually in conjunction with the registration renewal process.

- There were more nurses per 100,000 population in *Inner regional* areas than any other remoteness area (1,322 per 100,000). *Major cities* had the lowest rate of nurses per 100,000 population, followed by *Outer regional* (1,131 and 1235 per 100,000, respectively) (Table 3.14.62; Figure 3.14.7).

Table 3.14.62: Number of employed registered and enrolled nurses, by remoteness, 2009

	Major cities	Inner regional	Outer regional	Remote	Very remote	Not stated	Australia
Number	170,316	57,144	25,465	4,162	2,145	17,518	276,751
Nurses per 100,000 population	1,130.5	1,321.5	1,234.5	1,284.3	1,246.3	. .	1,260.7

Community housing

The 2006 CHINS collected information on health services from 1,187 discrete Indigenous communities. Information on distance to the nearest health facility, health professionals working within communities and access to medical emergency air services is presented below.

Distance to nearest health facility

- Of the 1,078 discrete Indigenous communities in 2006 that reported distance to the nearest health facility, 755 (70%) were located 100 kilometres or more from the nearest hospital (Table 3.14.63), compared with 841 (69%) in 2001. In 2006, these communities represented 56% of the reported population living in these discrete Indigenous communities compared with 53% in 2001.
- Aboriginal primary health-care centres and other (state-funded) community health centres were more likely to be located near or within Indigenous communities than were hospitals. In addition to the 9% of communities located with a hospital either in or within 10 kilometres of the community, 211 (20%) had an Aboriginal primary health-care centre located either in or within 10 kilometres of the community, and 217 (21%) had an other (state-funded) community health centre.
- Over half (56%) of the reported population living in discrete Indigenous communities that reported distance to the nearest health facility had an Aboriginal primary health-care centre in or within 10 kilometres of their community.

Health professionals within communities

- In 2006, over half (56%) of people living in discrete Indigenous communities located 10 kilometres or more from a hospital who completed the long community questionnaire had a male Indigenous health worker visit or work in their community on a daily basis, and almost three quarters (74%) had a female Indigenous health worker visit or work in their community on a daily basis (Table 3.14.64).
- Approximately 55,723 (91%) of these people had a registered nurse visiting or working in their community and 53,201 (87%) had a doctor visiting or working in their community (Table 3.14.64).
- Almost three quarters (73%) of these people had a registered nurse visit or work in the community on a daily basis and 19% had a doctor visit or work in the community on a daily basis (Table 3.14.64).
- Of the people living in discrete Indigenous communities with a population of fewer than 50 that are not self-administered, 32% had a male Indigenous health worker, 30% had a female Indigenous health worker, 32% had a registered nurse and 23% had a doctor visiting or working in their community.

Access to medical emergency air service

- In 2006, 316 (27%) discrete Indigenous communities had access to a medical emergency air service, accounting for 57% (52,936) of people living in discrete Indigenous communities (Table 3.14.65).
- Approximately half (49%) of communities with access to a medical emergency air service were located 250 kilometres or more from the nearest hospital.

Expenditure on health services

- It should be noted that the definition of health expenditure has changed from the 2008 HPF report and now excludes high-care residential aged care expenditure, which is instead classified as welfare expenditure (AIHW 2009). However, for the purposes of comparison information on high-care residential aged care is also presented.
- Expenditure on health and high-care residential aged care goods and services for Aboriginal and Torres Strait Islander people in 2008–09 was estimated at $3,700 million (Table 3.14.66). About 61% of this was for two areas of expenditure—services provided to admitted patients in public hospitals ($1,431 million) and community health services ($823 million).
- On a per person basis, estimated expenditure on health and high care aged care for Aboriginal and Torres Strait Islander people averaged $6,787, compared with $4,876 for non-Indigenous people—a ratio of 1.39:1.
- Per person expenditure on community health services for Indigenous Australians was nearly seven times that for non-Indigenous Australians. The per person ratio of Indigenous to non-Indigenous expenditure was also much higher for both patient transport and public health. Conversely, per person expenditure on aids and appliances for Indigenous was 20% of non-Indigenous per person expenditure. Expenditure on medications for Indigenous Australians was 50% of that of the non-Indigenous people.

Table 3.14.66: Total expenditure on health for Indigenous and non-Indigenous Australians, by area of expenditure, current prices, 2008–09

Data quality issues

Medicare data

MBS items

The MBS items included in this measure have been introduced over the last few years with the child health check item commencing in May 2006. The take-up of new MBS items is influenced by the speed at which practitioners and the population become aware of the new items and how to use them. Also take-up can be influenced by administrative processes and the time taken to change computer systems to incorporate these new items.

Standard Indigenous status question

In November 2002, the ABS standard question on Indigenous identification was included on Medicare enrolment forms. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Under-identification

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete. There were around 339,310 people who had identified as Aboriginal and/or Torres Strait Islander in this database at May 2012; around 59% of the estimated Aboriginal and Torres Strait Islander population (AHMAC 2012). There has been a rapid expansion in the number of enrolees who identified as Aboriginal and/or Torres Strait Islander, from 47,200 people in August 2004.

Readers should note the following caveats to the Medicare voluntary Indigenous Identifier (VII) adjustment methodology:

- Estimates generated by the adjustment methodology for a given period will vary according to the point in time at which they are calculated, as the adjustment factors will be updated regularly to account for the ongoing change in the population coverage of the VII sample.
- There are inherent uncertainties in the current ABS Indigenous population estimates, and they are therefore described by the ABS as 'experimental estimates and projections'. The ABS Indigenous population estimates after 2006–07 are experimental projections, based on a number of assumptions about future levels of fertility, mortality and migration. The projections are not predictions or forecasts, but are illustrations of the growth and change in population that would occur if these assumptions were to prevail over the projection period. There can be no certainty that any particular outcome will be realised, or that future outcomes will necessarily fall within the projected ranges.
- The propensity to identify as Aboriginal and/or Torres Strait Islander varies according to the motivations of the individual and the perceived uses of the data in question. For example, it is possible that there are some Aboriginal and Torres Strait Islander people who are registered with the VII but who do not identify as Indigenous for the purposes of the Census, or vice versa.
- In some areas, particularly remote and very remote areas, there is a portion of the Indigenous population that does not ever use the Medicare system. It is therefore possible that the adjustment methodology could overestimate Medicare use by the Indigenous population.

As the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could be biases in the data that are not addressed by the adjustment methodology.

DoHA general practice statistics

Care must be taken in using and interpreting the data provided. There are two issues to note which have an effect on the quality of the data. First, the data include only those services claimed through the Medicare system. Consequently the full-time equivalent for doctors in remote areas, which are more likely to have high proportions of Indigenous population, will be understated. This is because some services are provided in rural hospitals and through the Royal Flying Doctor Service. There is also anecdotal information that services provided in Aboriginal Medical Services are often not claimed through the Medicare system. This results in further understating the full-time equivalent for doctors in areas with high Indigenous populations.

Second, the data at the grouped SLA level can hide variability in data at the individual SLA level. For example, although one group of SLAs may have fewer people per doctor overall than a second group of SLAs, there will be a number of individual SLAs in the first group with far more people per doctor than in some individual SLAs in the second group.

OATSIH Service Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012a).

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of Newborn episodes that did not include qualified days, and records for Hospital boarders and Posthumous organ procurement have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in Major cities to 97% in Remote and Very remote areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011-12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021 (ABS 2009).

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It has therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities, Inner regional, Outer regional* and *Remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 National Health Surveys.

In remote communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

National Aboriginal and Torres Strait Islander Social Survey (NATSISS)

The NATSISS is conducted in all states and territories and includes remote and non-remote areas. The 2008 sample was 13,300 persons in 6900 households, with a response rate of 82% of households. Up to three randomly selected Indigenous people were chosen from selected households to participate in the survey. Trained ABS interviewers conducted the survey using face-to-face interviews. In non-remote areas, interviewers used a notebook computer to record responses, while in remote areas a paper questionnaire was used. Interviewers obtained the consent of a parent or guardian before interviewing those aged 15 to 17 years. Indigenous persons usually resident in non-private dwellings such as hotels, motels, hostels, hospitals, short-stay caravan parks, prisons and other correctional facilities were excluded.

The NATSISS uses the standard Indigenous status question. The NATSISS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians.

As with other surveys, the NATSISS is subject to sampling and non-sampling errors.

Care has been taken to ensure that the results of this survey are as accurate as possible. All interviews were conducted by trained ABS officers. However, some factors may affect the reliability of the data. Information recorded in this survey is 'as reported' by respondents, and therefore may differ from information available from other sources or collected using different methodologies.

Data on health-related indicators have been age-standardised to the 2001 total Australian population to account for differences in the age structures of the states and territories and the Indigenous and non-Indigenous population.

Time series comparisons for the 2008 survey are available through the 1994 National Aboriginal and Torres Strait Islander Survey and the 2002 NATSISS. However, not all data elements align across the three (1994, 2001 and 2008) NATSISS surveys, so care is required when reviewing results across the three surveys. There are no strictly comparable non-Indigenous results available for the 2008 NATSISS because the latest General Social Survey (which has been used in the past to compare with Indigenous results from the NATSISS) was run in 2006, with the next being run in 2010. Data from other ABS surveys run in 2008 may, however, be used to obtain rough non-Indigenous comparisons for some data items. Where possible, the ABS has provided recommendations for non-Indigenous data comparisons and these have been adopted in this report.

The 2008 NATSISS has a relatively large level of under-coverage when compared with other ABS surveys. There was also an increase in under-coverage compared with previous ABS Indigenous surveys. For example, the estimated under-coverage in the 2004–05 National Aboriginal and Torres Strait Islander Health Survey was 42%. The overall under-coverage rate for the 2008 NATSISS is approximately 53% of the in-scope population at the national level. This rate varies across the states and territories (ABS 2010).

Further information on NATSISS data quality issues can be found in the *2008 NATSISS user's guide* (ABS 2010).

Medical practitioners

The NHWDS: medical practitioners contains information sourced from registration data and workforce survey data.

The 2010 data collection is the first data release from the new national registration scheme. The data set is comprised of registration (including demographic) information provided by the Australian Health Practitioner Regulation Agency (AHPRA) and workforce details obtained by the Medical Workforce Survey. The survey instrument varies significantly in some areas from previous years, however, is now nationally consistent.

The 2010 collection excludes the workforce survey records of medical practitioners whose principal state of practice was Queensland and Western Australia, because not all registrations in Queensland and Western Australia expired on 30 September 2010, the date prescribed by AHPRA as the official closing data for registration renewal.

Estimates published from the Medical Workforce Survey 2010 are not directly comparable with estimates derived from the earlier AIHW Medical Labour Force Survey data. This is due to a change in the data collection methodology; including the survey design and questionnaire. For further information, refer to the Data Quality Statement and the online User guide for the NHWDS: medical practitioners 2010, available from the AIHW website.

AIHW Medical Labour Force Survey

The AIHW Medical Labour Force Survey is conducted on an annual basis. Survey responses are weighted by state, age and sex to produce state and territory and national estimates of the total medical labour force. Benchmarks for weighting come from registration information provided by state and territory registration boards.

The response rates to this survey can vary from year to year and across jurisdictions, but have stayed fairly stable over the five years to 2004. Note that the questionnaires have varied over time and across jurisdictions. Mapping of data items has been undertaken to provide time series data. However, because of this, and the variation in response rates, some caution should be used in interpreting change over time and differences across jurisdictions.

More detailed information about how these surveys were conducted is available from the report *Medical labour force 2009* (AIHW 2011d).

Community Housing and Infrastructure Needs Survey (CHINS)

The 2006 CHINS collected information on a variety of topics from discrete Aboriginal and Torres Strait Islander communities throughout Australia and on Indigenous organisations that provide rental housing to Indigenous people. In 2006, CHINS information was collected on 496 Indigenous organisations, which managed a total of 21,854 permanent dwellings. The majority of those dwellings were located in the Northern Territory (6,448), Queensland (6,230), New South Wales (4,176) and Western Australia (3,462) (ABS 2007).

The CHINS survey covers only discrete Indigenous communities. In 2006, the CHINS collected information from 1,187 discrete indigenous communities. This included approximately 92,960 Aboriginal and Torres Strait Islanders or 18% of the total Indigenous population. CHINS data are collected every five years. The data are collected from key personnel in Indigenous communities and housing organisations that are knowledgeable about housing and infrastructure issues.

The estimates are not subject to sampling error because the CHINS was designed as a complete enumeration of discrete Indigenous communities. However, data could not be obtained from a small number of communities. In addition, the community population was often estimated by community representatives without reference to records. Therefore, the data are subject non-sampling error.

Further information on the CHINS can be found in the publication *Housing and infrastructure in Aboriginal and Torres Strait Islander communities, Australia 2006* (ABS 2007).

Health Expenditure Data

The AIHW draws upon both expenditure data and service use data to prepare Indigenous health expenditure estimates.

The quality of Indigenous service use data is of varying quality, as there is widespread non-reporting of Indigenous status or under-identification in administration records. Although the quality of Indigenous service use data such as admitted patient data is improving, under-identification of Aboriginal and Torres Strait Islander people in these data sets remains a major issue.

The source of data used to estimate health expenditure for Indigenous and non-Indigenous Australians through Aboriginal Community Controlled Health Organisations (ACCHOs) has changed slightly for 2008-09 estimates. Past estimates for 2004-05 and 2006-07 used information from the Service Activity Report database, which was a joint project of the Office for Aboriginal and Torres Strait Islander Health (OATSIH) and the National Aboriginal Community Controlled Health Organisation. The database collected service level data on health care through an annual questionnaire completed by every Australian Government-funded Aboriginal and Torres Strait Islander primary health care service. In 2008–09, however, it was replaced with the new OATSIH Service Report database, which also includes data previously collected under the Drug and Alcohol Service Report, and Bringing Them Home and Link Up Counsellors data collections.

Under-identification

Estimates of the level of Indigenous under-identification were used to adjust admitted patient expenditure estimates for New South Wales, Victoria, Queensland, South Australia, Western Australia and the Northern Territory (public hospitals only). In some states and territories, a single state-wide average under-identification adjustment factor was applied. In others, differential under-identification factors were used, depending on the region in which particular service(s) were located (AIHW 2011b).

As the AIHW studies on Indigenous identification in hospitalisation data did not include private hospitals, an adjustment factor of 54% for private hospitals was derived from the analysis of linked hospital morbidity data from New South Wales.

Expenditure estimates

Some of the expenditure patterns in this report may be influenced by variations in the completeness of Indigenous identification, despite the adjustments made for under-identification. The use of scaled up MBS and PBS data based on the level of VII enrolment is one such example. It is possible that health expenditure estimates for Aboriginal and Torres Strait Islander people may slightly overestimate or underestimate the actual level of health expenditure. As a result, estimating health expenditure for Indigenous Australians is an evolving field, and conclusions should be drawn with caution.

In addition, while every effort has been made to ensure consistent reporting and categorisation of expenditure on health goods and services, in some cases there are inconsistencies across expenditure data providers. These result from limitations of financial reporting systems and/or different reporting mechanisms.

Time series estimate comparisons

The definition of health expenditure changed in 2007 to exclude high-care residential aged care, which was instead classified as welfare expenditure. For the purpose of comparison, high-care residential aged care expenditure has been omitted from all of the years' estimates to allow for the comparison of health expenditure estimates over time.

There was a change in the method for estimating MBS and PBS expenditure for the 2006–07 and 2008–09 reports in this series. The revised method involves the use of Medicare VII data to estimate expenditure on medical services, such as general practitioner, specialist services, pathologist services, imaging services, and prescription pharmaceuticals provided to Aboriginal and Torres Strait Islander people. Prior to this, data from the Bettering the Evaluation and Care of Health (BEACH) survey data were used in these estimates. This change may have contributed to the increase in MBS and PBS expenditure estimates in 2006–07 and 2008–09 reports compared with those in the 2001–02 and 2004–05 reports (AIHW 2011b).

Palliative care data

Data on palliative care are sourced from the Admitted Patient Palliative Care National Minimum Data Set (NMDS). The NMDS is a component of the National Hospital Morbidity Data Collection (NHMD). This is the most developed data collection currently available for reporting on palliative care services. Further details on the Admitted Patient Care NMDS methodology presented here can be found in the 2011 publication *Identifying palliative care hospitalisations in admitted patient data: technical paper* (AIHW 2011c) and the *Trends in palliative care in Australian hospitals* publication (AIHW 2011f).

Palliative care in the admitted patient setting may be provided in a hospice, in a dedicated palliative care ward or other wards within a hospital.

A palliative care separation is defined as an episode of admitted patient care for which the principal clinical intent was palliation during all or part of that episode. Two NHMD data items — 'Care type' and 'Diagnosis' capture information on palliative care, such that if either (or both) has a code of Palliative care, that separation is included. As such, it is important to note that this means that although there may also be other separations within the NHMD which include palliative care services, these separations are not counted due to the fact that palliative care is not recorded as the main care type and/or diagnosis during the separation.

Hospital data on palliative care is likely to include similar data quality problems to those outlined in the hospital separations data section above.

List of tables

List of figures

3.15 Access to prescription medicines

This measure has two components:

- **Pharmaceutical Benefits Scheme expenditure per capita for Indigenous Australians**
- **Pharmacy labour force.**

Data sources

Data for this measure come from AIHW health expenditure data and the AIHW Pharmacists Labour Force Survey

Health expenditure data

The AIHW reports biennially on expenditure on health for Aboriginal and Torres Strait Islander people. The latest report in the series, *Expenditure on health for Aboriginal and Torres Strait Islander people 2008–09,* was released in 2011.

The AIHW draws upon both expenditure data and service use data to prepare Indigenous health expenditure estimates. The total expenditure and revenue data used to generate the tables are mainly administrative by-products of the accounting process, and are, as much as possible, produced on an accrual basis. Service use data, where available, provide demographic information about who is actually using the services provided.

Information obtained from Medicare Voluntary Indigenous Identifier (VII) data have been used to estimate MBS and PBS expenditure for Aboriginal and Torres Strait Islander people. The source of data used to estimate health expenditure for Indigenous and non-Indigenous Australians through Aboriginal Community Controlled Health Organisations (ACCHOs) comes from the OATSIH Service Report database.

AIHW Pharmacists Labour Force Survey

The AIHW runs a number of surveys of the health labour force including the Pharmacy Labour Force Survey (AIHW 2003). The AIHW is the data custodian of this collection. The survey is of registered pharmacists and is drawn from the registration files maintained by each state and territory pharmacy registration board. Each pharmacy board conducts an annual renewal of registration and, in some years, questionnaires are sent to pharmacists on renewal of their registration. It covered all pharmacists registered with the pharmacy board in each state and territory, but may have excluded pharmacists who registered for the first time in the survey year. In 2003 the survey was conducted in all jurisdictions except the Northern Territory. The response rate to the survey was 76.3% (AIHW 2003).

There is currently no data source for statistics on not filling prescriptions because of cost for Indigenous Australians.

Analyses

Pharmaceuticals expenditure

- Expenditure on medications provided by the Australian Government for Aboriginal and Torres Strait Islander people in 2008–09 was estimated at $143.9 million, which represented 1.8% of total expenditure on pharmaceuticals in Australia by the Australian Government (Table 3.15.1). Non-government expenditure on pharmaceuticals for Indigenous people was estimated at $27.9 million, which represented 0.4% of total expenditure on pharmaceuticals by non-government organisations.
- The majority of expenditure on these pharmaceuticals was for benefit-paid pharmaceuticals ($133.6 million of Australian Government expenditure and $5.3 million of non-government expenditure).
- Per capita expenditure on pharmaceuticals by the Australian Government for 2008–09 was estimated at $264 for Indigenous people and $362 for non-Indigenous people—a ratio of 0.7:1. Per capita non-government expenditure on pharmaceuticals was estimated at $51 for Indigenous people and $298 for non-Indigenous people—a ratio of 0.1:1.

Table 3.15.1: Total and per person expenditure (current prices) on pharmaceuticals by the Australian Government and non-government organisations, by Indigenous status, 2008–09

	Total expenditure ($ million)			Expenditure per person ($)		
PBS	Indigenous	Non-Indigenous	Indigenous share (%)	Indigenous	Non-Indigenous	Ratio
Australian Government						
Benefit-paid pharmaceuticals[(a)]	133.6	6,956.5	1.9	245.1	328.4	0.7
Other pharmaceuticals	10.3	705.0	1.4	18.9	33.3	0.6
Total pharmaceuticals	**143.9**	**7,661.5**	**1.8**	**264.0**	**361.7**	**0.7**
Non-Government						
Benefit-paid pharmaceuticals[(a)]	5.3	1,446.50	0.4	9.8	68.3	0.1
Other pharmaceuticals	22.6	5,926.50	0.4	41.5	279.8	0.2
Total pharmaceuticals	**27.9**	**7373**	**0.4**	**51.3**	**348.1**	**0.1**
Total						
Benefit-paid pharmaceuticals	138.9	8,403.0	1.6	254.9	396.7	0.6
Other pharmaceuticals	32.9	6,631.5	0.5	60.4	313.1	0.2
Total pharmaceuticals	**171.8**	**15,034.5**	**1.1**	**315.3**	**709.8**	**0.4**

(a) Includes the Repatriation Pharmaceutical Benefits Scheme (RPBS) as well as the PBS.

Source: AIHW 2011.

PBS expenditure

- In 2008–09, benefits to Indigenous Australians through the Pharmaceutical Benefits Scheme were estimated at $136 million. Pharmaceutical benefits expenditures per person for Indigenous Australians were 70% of the non-Indigenous average (Table 3.15.2). The average per person share of expenditure on mainstream pharmaceutical benefits was also lower, at 60%.

- In 1999, special provisions were introduced under Section 100 of the *National Health Act 1953* for Indigenous Australians in remote areas where access to private pharmacies was poor. Clients of approved remote area Aboriginal Health Services (AHS) were able to receive PBS medicines directly from the AHS at the time of medical consultation without the need for a normal prescription form, and without charge. Estimated expenditure on Indigenous Australians in 2008–09 on drugs dispensed under this Act was $29.5 million. The estimated ratio of Indigenous to non-Indigenous expenditure per person under the scheme was 259:1.

Table 3.15.2: Total and per person expenditures through the Pharmaceutical Benefits Scheme, by Indigenous status, 2008–09[(a)][(b)]

	Total expenditure ($ million)			Expenditure per person ($)		
Pharmaceutical benefits	**Indigenous**	**Non-Indigenous**	**Indigenous share (%)**	**Indigenous**	**Non-Indigenous**	**Ratio[(c)]**
Mainstream PBS	97.5	6,481.0	1.5	178.8	306.0	0.6
Section 100	29.5	4.4	87.0	54.2	0.2	259.4
Other PBS special supply	9.4	668.5	1.4	17.2	31.6	0.5
Total PBS	**136.4**	**7,154.0**	**1.9**	**250.2**	**337.7**	**0.7**

(a) Includes Australian Government Department of Health and Ageing expenditure only.

(b) Excludes RPBS, and highly specialised drugs dispensed from public and private hospitals.

(c) Ratio calculation is based on unrounded numbers.

Source: AIHW 2011.

PBS expenditure by remoteness

- In 2008–09, PBS pharmaceutical expenditures on Indigenous people were greater in *Remote* and *Very remote* areas, where the Section 100 arrangements apply, ($304 per person) than in *Inner regional* ($252 per person) (Table 3.15.3).

Table 3.15.3: Estimated average health expenditures per person on pharmaceutical benefits, for Aboriginal and Torres Strait Islander people, by remoteness, 2008–09

	Expenditure per person ($)				
	Major cities	**Inner regional**	**Outer regional**	**Remote and very remote**	**All regions**
PBS pharmaceuticals	250.6	252.3	189.3	304.2	250.2

Note: PBS drugs include $19.4 million of Section 100 Remote Area Health Services expenditure. Almost all of this expenditure occurs in remote and very remote areas.

Source: AIHW 2011.

PBS expenditure over time

Changes in expenditure over time should be interpreted with caution because of differences in methodology used to calculate some Indigenous expenditure estimates for different time periods. The following estimates are presented in constant 2008–09 dollars.

- The estimates of average expenditure per person for the Indigenous population by the Australian Government on the PBS between 2001–02 and 2004–05 increased by 85% from an estimated $74.3 in 2001–02 to $137.8 in 2004–05. Expenditure increased by another

28% between 2004–05 and 2006–07 (from $137.8 to $176.2) and by another 42% between 2006–07 and 2008–09 (from $176.2 to $250.2).

- The Indigenous to non-Indigenous expenditure ratios were higher in 2008–09 than in 2001–02 (0.7 compared with 0.3) (Table 3.15.4). Average annual growth for Indigenous Australians was 19 per cent for Indigenous Australians and nearly 6 per cent for non-Indigenous Australians.

Table 3.15.4: Average PBS(a) health expenditure (constant prices(b)) per person(c) by the Australian Government, 2001–02 to 2008–09

	Indigenous(d)	**Non-Indigenous**	**Ratio**	**Rate Difference**
2001–02	74.3	226.9	0.3	–152.7
2004–05	137.8	275.7	0.5	–137.9
2006–07	176.2	292.0	0.6	–115.8
2008–09	250.2	337.7	0.7	–87.6
Average annual growth (per cent)	18.9	5.8	. .	. .
Growth 2001–02 to 2008–09 (per cent)(e)	236.9	48.8	. .	. .

(a) Excludes RPBS, and highly specialised drugs dispensed from public and private hospitals.

(b) Constant price health expenditure for 2001–02 to 2008–09 is expressed in terms of 2008–09 prices.

(c) Indigenous population estimates used to estimate the expenditure figures are all derived from 2006-census base.

(d) 2001–02 and 2004–05 estimates for Indigenous population are based on BEACH survey, while estimates for following years are based on Medicare's Voluntary Indigenous Identifier data.

(e) Per cent change between 2001 and 2009 based on the average annual change over the period.

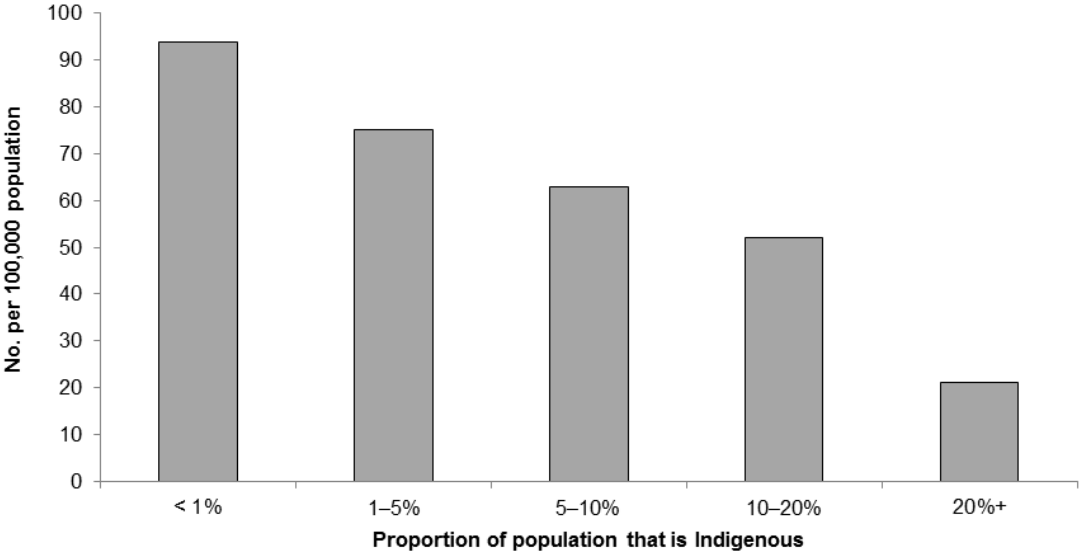
Source: AIHW.

Pharmacy labour force

Information on pharmacists in Australia is available from the AIHW Pharmacy Labour Force Survey. Response to the Pharmacy Labour Force Survey in 2003 represented 76.3% of pharmacist registrations in all participating jurisdictions. The overall response rate is an approximation because some pharmacists were registered in more than one state or territory. The AIHW uses data collected in the Pharmacy Labour Force Survey to derive estimates of the total pharmacy labour force. Survey responses are weighted to account for non-response (AIHW 2003).

Data presented below shows the FTE rate of employed pharmacists per 100,000 population by areas of low through to high proportions of Indigenous populations. Using population data from the 2001 Census, Statistical Local Areas (SLAs) were grouped according to the proportion of the population living in these areas that was Indigenous.

- In 2003, there were 15,673 employed pharmacists in Australia. The FTE rate of employed pharmacists was around 85 per 100,000 (Table 3.15.5).
- The number of full-time equivalent pharmacists per 100,000 population declined with remoteness, from 92 per 100,000 in major cities to 39 per 100,000 in very remote areas (Table 3.15.5).
- The FTE rate of employed pharmacists was highest in areas where less than 1% of the population was Indigenous (94 per 100,000) and lowest in areas where 20% or more of the population were Indigenous (21 per 100,000) (Figure 3.15.1 and Table 3.15.6).



Notes

1. In 2003, 808 employed pharmacists did not report the postcode they worked in. Hence the number of employed pharmacists stated by region is an underestimate.
2. Data do not include Northern Territory.
3. FTE is based on 35 hours per week.
4. Data from Victoria are based on 2004 survey data weighted to 2005 registration data.

Data quality issues

Health Expenditure Data

The AIHW draws upon both expenditure data and service use data to prepare Indigenous health expenditure estimates.

The quality of Indigenous service use data is of varying quality, as there is widespread non-reporting of Indigenous status or under-identification in administration records. Although the quality of Indigenous service use data such as admitted patient data is improving, under-identification of Aboriginal and Torres Strait Islander people in these data sets remains a major issue.

The source of data used to estimate health expenditure for Indigenous and non-Indigenous Australians through Aboriginal Community Controlled Health Organisations (ACCHOs) has changed slightly for 2008–09 estimates. Past estimates for 2004–05 and 2006–07 used information from the Service Activity Report database, which was a joint project of the Office for Aboriginal and Torres Strait Islander Health (OATSIH) and the National Aboriginal Community Controlled Health Organisation. The database collected service level data on health care through an annual questionnaire completed by every Australian Government-funded Aboriginal and Torres Strait Islander primary health care service. In 2008–09, however, it was replaced with the new OATSIH Service Report database, which also includes data previously collected under the Drug and Alcohol Service Report, and Bringing Them Home and Link Up Counsellors data collections.

Under-identification

Estimates of the level of Indigenous under-identification were used to adjust admitted patient expenditure estimates for New South Wales, Victoria, Queensland, South Australia, Western Australia and the Northern Territory (public hospitals only). In some states and territories, a single state-wide average under-identification adjustment factor was applied. In others, differential under-identification factors were used, depending on the region in which particular service(s) were located (AIHW 2011).

As the AIHW studies on Indigenous identification in hospitalisation data did not include private hospitals, an adjustment factor of 54% for private hospitals was derived from the analysis of linked hospital morbidity data from New South Wales.

Expenditure estimates

Some of the expenditure patterns in this report may be influenced by variations in the completeness of Indigenous identification, despite the adjustments made for under-identification. The use of scaled up MBS and PBS data based on the level of VII enrolment is one such example. It is possible that health expenditure estimates for Aboriginal and Torres Strait Islander people may slightly overestimate or underestimate the actual level of health expenditure. As a result, estimating health expenditure for Indigenous Australians is an evolving field, and conclusions should be drawn with caution.

In addition, while every effort has been made to ensure consistent reporting and categorisation of expenditure on health goods and services, in some cases there are inconsistencies across expenditure data providers. These result from limitations of financial reporting systems and/or different reporting mechanisms.

Time series estimate comparisons

The definition of health expenditure changed in 2007 to exclude high-care residential aged care, which was instead classified as welfare expenditure.

For the purpose of comparison, high-care residential aged care expenditure has been omitted from all of the previous years' estimates to allow for the comparison of health expenditure estimates over time.

There was a change in the method for estimating MBS and PBS expenditure for the 2006–07 and 2008–09 reports in this series. The revised method involves the use of Medicare VII data to estimate expenditure on medical services, such as general practitioner, specialist services, pathologist services, imaging services, and prescription pharmaceuticals provided to Aboriginal and Torres Strait Islander people. Prior to this, data from the Bettering the Evaluation and Care of Health (BEACH) survey data were used in these estimates. This change may have contributed to the increase in MBS and PBS expenditure estimates in 2006–07 and 2008–09 reports compared with those in the 2001–02 and 2004–05 reports (AIHW 2011).

AIHW Pharmacists Labour Force Survey

Pharmacists may register in more than one state or territory. In estimating the pharmacy labour force, it is therefore important to reduce as much as possible the consequent duplication in statistics.

The estimation of the number and characteristics of currently employed pharmacists in each state and territory was based on the responses of those pharmacists employed solely or mainly in the state or territory of registration. Pharmacists who were on leave for three months or more, although employed, were excluded from most tables of employed pharmacists because not all states and territories collected data on pharmacists who were on leave.

List of figures

3.16 Access to after-hours primary health care

Access to after-hours primary health care by Aboriginal and Torres Strait Islander people

Data sources

Data for this measure come from the Bettering the Evaluation and Care of Health (BEACH) survey, the OATSIH Services Reporting (OSR) Data Collection, Medicare data and the Non-admitted Patient Emergency Department Care National Minimum Data Set.

Bettering the Evaluation and Care of Health (BEACH) Survey

Information about encounters in general practice is available from the BEACH survey, which was conducted by the AIHW Australian General Practice Statistics and Classification Centre, in the Family Medicine Research Centre (FMRC) at the University of Sydney until March 2012, when the AIHW ceased its involvement in the BEACH program . The FMRC continues to run BEACH the results are now published by the University of Sydney. The most recent annual reports can be found at http://ses.library.usyd.edu.au/handle/2123/7771.

Information is collected from every changing random sample of approximately 1,000 general practitioners (GPs) from across Australia each year. A sample of 100 consecutive GP–patient encounters is collected by each GP.

The number of Indigenous patients identified in the BEACH survey is likely to be underestimated because some GPs might not ask the question on Indigenous status, or the patient may choose not to identify themselves (AIHW 2002).

Data are presented for the 5-year period 2006–07 to 2010–11, during which there were around 6,000 GP encounters with Aboriginal and Torres Strait Islander patients recorded in the survey, representing 1.2% of total GP encounters.

OATSIH Services Reporting data collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in

earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Medicare database

Medicare enrolment application forms are lodged by persons wishing to enrol with Medicare at Medicare offices in each state/territory or by mail. Information from these forms is entered directly into the Medicare database, which is held by the Department of Health and Ageing (DoHA).

In November 2002, the ABS standard question on Indigenous identification was included on this form. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete.

As at 1 May 2012, 339,310 Indigenous Australians were enrolled on the VII database. This represents 59% of the estimated total Indigenous population (AHMAC 2012).

Medicare data presented in this report have been adjusted for under-identification. There are a number of caveats to the VII adjustment methodology, including that as the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could therefore be biases in the data that are not addressed by the adjustment methodology.

National Non-admitted Patient Emergency Department Care Database

The National Non-admitted Patient Emergency Department Care Database (NAPEDCD) is a national collection of de-identified data on emergency department episodes held at the AIHW. The database includes episode-level data on non-admitted patients treated in the emergency departments of public hospitals. These hospitals are classified in the public hospital peer groups of principal referral and specialist women's and children's hospitals and large hospitals. Data excludes patients who were admitted or arrived at the hospital by ambulance.

The NAPEDCD includes data on the type and length of emergency department visit, triage category, waiting times, patient demographics, arrival mode and departure status.

This data set includes the standard Indigenous status question. The identification of Indigenous patients is not considered complete and varies among jurisdictions.

It is recommended that these data only be reported as numbers and proportions and not rates, because the denominator would include Indigenous Australians not covered in this collection. The quality of the data reported for Indigenous status in emergency departments has not been formally assessed; most states and territories advised that the Indigenous status data collected in an emergency department setting could be less accurate than the data collected for admitted patients (AIHW 2012a).

Analyses

General practitioner data (BEACH)

The BEACH Survey collected information on the after-hours arrangements of GPs surveyed. GPs can have more than one type of after-hours arrangement.

- For the BEACH reporting period April 2010–March 2011, around 99% of GPs surveyed worked in practices with after-hours arrangements in place. For 30% of GPs, the practice had its own after-hours arrangements; 14% of GPs had cooperative arrangements with other practices regarding after-hours care; 52% employed a deputising service for after-hours patient care, and 10% had other after-hours arrangements (Britt et al. 2011).

The BEACH survey also collected information on GP encounters with Indigenous patients and other patients. Table 3.16.1 and Figure 3.16.1 present the rate of GP encounters with Indigenous and other patients by whether the GP visited had after-hours arrangements in place at their practice.

- Over the five year BEACH period April 2006–March 2007 to April 2010–March 2011, 90% of encounters with Indigenous patients, and 98% of encounters with other patients, were with GPs with after-hours arrangements (Table 3.16.1).
- At approximately 34% of GP encounters with Indigenous patients, the GP visited had their own after-hours arrangements for patient care; for 13% the GP had cooperative arrangements with other practices; for 25% the GP employed a deputising service for after-hours patient care; for 34% the GP had other after-hours arrangements in place. For nearly 10% of encounters with Indigenous patients, the GP visited had no after-hours arrangements in place (Table 3.16.1).
- The proportion of encounters with GPs at practices that employed other after-hours arrangements including referred to another service for after-hours patient care was higher for encounters with Indigenous patients than for encounters with other patients (27% compared with 15% respectively). Fewer encounters with Indigenous patients were with GPs at practices that employed a deputising service for after-hours patient care than other patient encounters (25% compared with 53%) (Table 3.16.1; Figure 3.16.1).

Table 3.16.1: GP encounters by whether the GP has after-hours arrangements, by Indigenous status, BEACH years April 2006–March 2007 to April 2010–March 2011[a]

Figure 3.16.1: Rate of GP encounters, by whether the GP has after-hours arrangements in place, by Indigenous status of the patient, BEACH years April 2006–March 2007 to April 2010–March 2011

After-hours services provided by GPs (Medicare data)

Information on the number of after-hours services provided by GPs working in Australia is available from the DoHA using the MBS items for after-hours services (1, 2, 97–98, 500–5067, 5200–5267, 601–602, 697 and 698).

A service refers to a claim for a single MBS item. There may be more than one service provided for each patient episode of care.

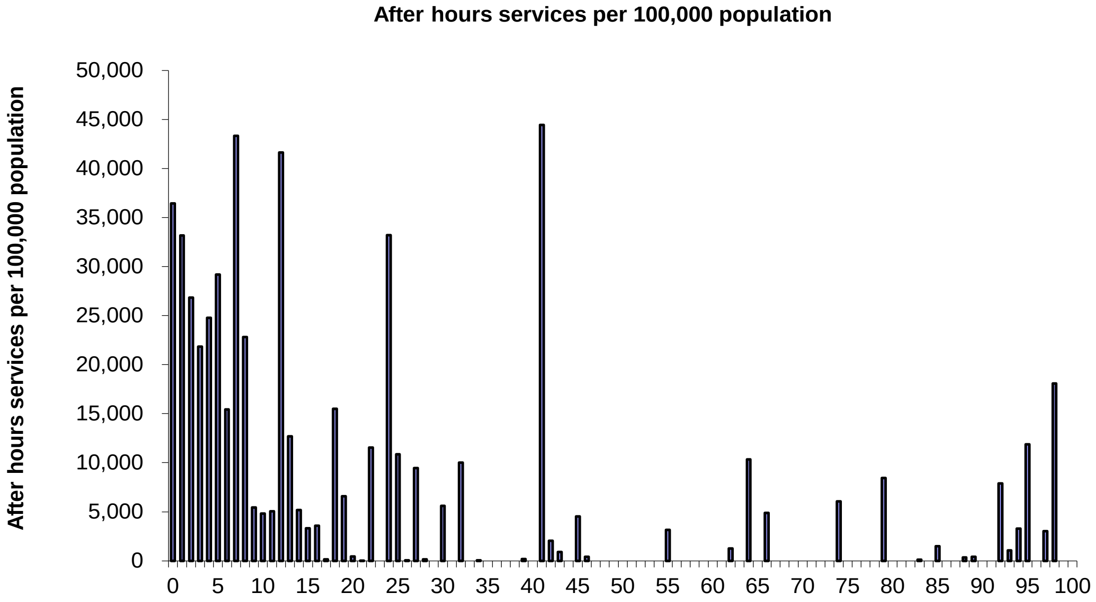
Data in Figure 3.16.2 present the number of after-hours services provided by full-time equivalent GPs per 100,000 population by areas of low through to high proportions of Indigenous people in the population. Using population data from the 2001 Census, Statistical Local Areas (SLAs) were grouped according to the proportion of the population living in these areas that was Indigenous. Note that the use of proportions of Indigenous populations does not show the number of Indigenous persons actually claiming after-hours services.

- In 2010–11, there were 16,926 full-time equivalent GPs working in Australia who provided 6,167,513 after-hours services to patients.
- Across Australia, the rate of after-hours services provided by GPs was around 29,798 per 100,000 population. The provision of after-hours services tends to be lower in regions where Indigenous Australians are a higher proportion of the population (Figure 3.16.2).

Care must be taken in using and interpreting the data provided. There are three issues to note that have an effect on the quality of the data. First, the data include only those services claimed through the Medicare system. Consequently, the full-time equivalent (FTE) for doctors in remote areas, which are more likely to have high proportions of Indigenous population, will be understated because some services are provided in rural hospitals and through the Royal Flying Doctor Service. There is also anecdotal information that services provided in Aboriginal Medical Services are often not claimed through the Medicare system—further understating the FTE for doctors in areas with high Indigenous populations.

Secondly, the data at the grouped SLA level can hide variability in data at the individual SLA level. For example, although one group of SLAs may have fewer people per doctor overall than a second group of SLAs, there will be a number of individual SLAs in the first group with far more people per doctor than some of the individual SLAs in the second group.

Thirdly, these data do not measure Indigenous Australians use of after-hours MBS items. They are a substitute measure based on after-hours MBS claims for the whole population in relation to the size of the Indigenous population in each SLA.



Note: Results for SLAs where the number of after-hours services is less than three have been suppressed.

Source: AIHW analysis of Medicare Database.

Figure 3.16.2: Rate of after-hours services provided by FTE GPs in areas of low through to high proportions of Indigenous people in the population, 2010–11

Aboriginal and Torres Strait Islander primary health-care services

Information on Aboriginal and Torres Strait Islander primary health-care services that provided care outside of normal operating hours is available from the 2010–11 OSR database.

- In 2010–11, 55% of OATSIH funded Aboriginal and Torres Strait Islander Primary health care services provided health care services outside of normal operating hours.
- The most common types of service provided outside of normal operating hours by Indigenous primary health-care services were emotional and social well-being/mental health services (69%) and transport (68%). Other services include: transfer/ admission to hospital (66%); diagnosis and treatment of illness /disease (58%); antenatal /maternal care (53%); treatment of injury (53%); hospital inpatient/ outpatient care (28%); and care in police station/lock-up/prison(24%) (Table 3.16.2).

Table 3.16.2: Number and proportion of Aboriginal and Torres Strait Islander primary health care services that provided care outside of normal operating hours, by type of service, 2010–11

Provider of after-hours services	No. services	Per cent
Provided after-hours services[(a)]	129	55.4
Did not provide after-hours services[(a)]	104	44.6
Type of after-hour service[(b)]		
Transport	88	68.2
Transmission/admission to hospital	85	65.9
Emotional and social wellbeing/ mental health	89	69.0
Diagnosis and treatment of illness/disease	75	58.1
Treatment of injury	68	52.7
Antenatal/maternal care	68	52.7
Hospital inpatient/outpatient care	36	27.9
Care in police station/ lock-up/ prison	31	24.0
Other	25	19.4
Provided after-hours services[(b)]	**129**	**55.4**
Not stated whether provide after-hours services	2	. .
Reported whether provide after-hours services	233	. .
Total primary health care services	**235**	**100.0**

(a) Two hundred and thirty three of the 235 respondent Aboriginal and Torres Strait Islander primary health-care services provided information on whether they provided after hours care.

(b) 129 of the 233 respondent Aboriginal and Torres Strait Islander primary health-care services provided information on the type of after-hours care their service provided. These percentages are calculated as a proportion of these 129 services.

Source: AIHW OSR data collection.

Emergency department episodes

Information on non-admitted patients treated in the emergency departments of public hospitals that were classified in the public hospitals is available from the AIHW NAPEDCD. Note that this data set only includes hospitals that were classified in the public hospital peer groups of 'principal referral' as 'specialist women's and children's hospitals' or 'large hospitals'. These hospitals are predominantly in *Major cities*. Therefore, the episodes of care reported underestimate the level of use of emergency department services by Indigenous Australians nationally.

- In 2008–09 to 2009–10, there were 11,687,722 episodes of care provided by emergency departments, 533,170,115 (4.6%) of which were for patients identified as Aboriginal or Torres Strait Islander (Table 3.16.3).
- In 2008–09 to 2009–10, there were 6,818,526 episodes of care provided by emergency departments for triage categories 4 (semi-urgent) and 5 (non-urgent), of which 335,796 (4.9%) were for patients identified as Indigenous (Table 3.16.4).
- In 2008–09 to 2009–10, there were 6,544,546 episodes of care provided after-hours in emergency departments, of which 307,001 (4.7%) were for patients identified as Indigenous. Over half of all presentations to emergency departments by Indigenous and non-Indigenous patients were for after-hours care (58% and 56%, respectively) (Table 3.16.5).
- Around one-quarter of all presentations to emergency departments by Indigenous patients were after-hours on weekends, 15% were on Sundays and 11% were before 8 am or after 1 pm on Saturdays (Table 3.16.5).
- In 2008–09 to 2009–10, there were 3,699,896 episodes of care provided after-hours in emergency departments for triage categories 4 (semi-urgent) and 5 (non-urgent), of which 185, 864 (5%) were for patients identified as Indigenous. Around half of all presentations to emergency departments for triage categories 4 (semi-urgent) and 5 (non-urgent) by Indigenous and non-Indigenous patients were for after-hours care (both 46%) (Table 3.16.6).
- Around one-quarter of all presentations to emergency departments for triage categories 4 (semi-urgent) and 5 (non-urgent) by Indigenous patients were after-hours on weekends, 16% were on Sundays and 11% were before 8 am or after 1 pm on Saturdays (Table 3.16.6).
- The proportion of presentations to emergency departments after hours by Indigenous patients varied by jurisdiction, South Australia had the highest proportion (61%) and Tasmania the lowest (55%) (Table 3.16.7). The Australian Capital Territory and New South Wales had the highest proportion (58%) of Indigenous presentations to emergency departments after hours for semi-urgent and non-urgent triage categories and Tasmania the lowest (52.3%) (Table 3.16.8).

Total	**533,170**	**10,573,478**	**581,074**	**100.0**	**100.0**	**100.0**

Notes

1. The non-admitted patient emergency department care data are required to be reported for hospitals categorised as peer group A or B in the previous year's Australian hospital statistics. In addition, data are provided for some smaller hospitals by some states and territories.
2. The coverage of the National Non-admitted Patient Emergency Department Care Database is estimated at about 80% of records for 2008–09 and 81% for 2009–10. Therefore this data will only cover a subset of after-hours emergency department presentations.
3. The quality of the identification of Indigenous patients in National Non-admitted Patient Emergency Department Care Database has not been assessed. Identification of Indigenous patients is not considered to be complete, and completeness may vary among the states and territories’.

Data quality issues

General Practitioner Data (BEACH)

Information about general practitioner encounters is available from the Bettering the Evaluation and Care of Health (BEACH) survey. The BEACH data on Indigenous Australians should be treated with care. First, the sample has not been designed to produce statistically significant results for population subgroups such as Indigenous Australians. Second, the identification of Indigenous Australians is not complete. Although the questionnaire contains an Indigenous identifier, it is unknown whether all GPs ask their patients this question. In the BEACH survey, 'not stated' responses to the Indigenous identification question are often higher than the 'yes' responses. It can be assumed, therefore, that the survey consistently undercounts the number of Indigenous Australians visiting general practitioners. Further detailed analyses of this issue are covered in *General practice in Australia, heath priorities and policies 1998 to 2008*, (Britt & Miller 2009:101):

'The findings of a BEACH substudy confirmed this suspected under-identification. In the data period reported here, 1.4% of patients encountered identified themselves as Indigenous. In contrast, in a BEACH substudy that asked 9,245 patients a complete set of questions about their cultural background (including Indigenous status) 2.2% (95% CI: 1.6–2.9) of respondents identified themselves as Indigenous (Britt et al. 2007). This rate is similar to the ABS estimates of Indigenous Australians as a proportion of the total population (ABS 2006).

However, the BEACH substudy included Indigenous Australians seen at Community Controlled Health Services funded through Medicare claims, and the estimate of 2.2% could have been an overestimate for the proportion of encounters that are with Indigenous patients in general practice as a whole. Deeble et al. (2008) conducted further investigations on this data and estimated that the BEACH encounter identification was an underestimate of about 10%, and that a more reliable estimate of the Indigenous population would be about 1.6% of all encounters (Deeble et al. 2008).

The findings of these studies are that some GPs are not routinely asking patients at the encounter about their Indigenous status, even when this is a variable specifically collected for each patient encountered, as it is in BEACH encounter data.'

OATSIH Service Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012b).

Medicare data

MBS items

The MBS items included in this measure have been introduced over the last few years with the child health check item commencing in May 2006. The take-up of new MBS items is influenced by the speed at which practitioners and the population become aware of the new items and how to use them. Also take-up can be influenced by administrative processes and the time taken to change computer systems to incorporate these new items.

Standard Indigenous status question

In November 2002, the ABS standard question on Indigenous identification was included on Medicare enrolment forms. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Under-identification

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete. There were around 339,310 people who had identified as Aboriginal and/or Torres Strait Islander in this database at May 2012; around 59% of the estimated Aboriginal and Torres Strait Islander population (AHMAC 2012). There has been a rapid expansion in the number of enrolees who identified as Aboriginal and/or Torres Strait Islander, from 47,200 people in August 2004.

Readers should note the following caveats to the Medicare voluntary Indigenous Identifier (VII) adjustment methodology:

- Estimates generated by the adjustment methodology for a given period will vary according to the point in time at which they are calculated, as the adjustment factors will be updated regularly to account for the ongoing change in the population coverage of the VII sample.
- There are inherent uncertainties in the current ABS Indigenous population estimates, and they are therefore described by the ABS as 'experimental estimates and projections'. The ABS Indigenous population estimates after 2006–07 are experimental projections, based on a number of assumptions about future levels of fertility, mortality and migration. The projections are not predictions or forecasts, but are illustrations of the growth and change in population that would occur if these assumptions were to prevail over the projection period. There can be no certainty that any particular outcome will be realised, or that future outcomes will necessarily fall within the projected ranges.
- The propensity to identify as Aboriginal and/or Torres Strait Islander varies according to the motivations of the individual and the perceived uses of the data in question. For example, it is possible that there are some Aboriginal and Torres Strait Islander people who are registered with the VII but who do not identify as Indigenous for the purposes of the Census, or vice versa.
- In some areas, particularly remote and very remote areas, there is a portion of the Indigenous population that does not ever use the Medicare system. It is therefore possible that the adjustment methodology could overestimate Medicare use by the Indigenous population.
- As the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could be biases in the data that are not addressed by the adjustment methodology.

National Non-admitted Patient Emergency Department Care Database

The National Non-admitted Patient Emergency Department Care Database is a national collection of de-identified data on emergency department episodes based on the Non-admitted Emergency Department Care National Minimum Data Set. The non-admitted patient emergency department care data are required to be reported for hospitals categorised as peer group A or B in the previous year's Australian hospital statistics. In addition, data are provided for some smaller hospitals by some states and territories.

For 2009–10, all states and territories provided episode-level data to the NNAPEDCD for all public hospitals in peer groups A and B that had emergency departments (that is 100% of hospitals that were required to report episode-level data). Data excludes patients who were admitted or arrived at the hospital by ambulance.

Indigenous status question

This data set includes the standard Indigenous status question.

Under-identification

The quality of the data provided for Indigenous status in 2007–08 for emergency department presentations varied by jurisdiction. Most states and territories advised that the Indigenous status data collected in an emergency department setting could be less accurate than the data collected for admitted patients; the data should therefore be used with caution (AIHW 2010). It is recommended that these data only be reported as numbers, and not rates, because the denominator would include Indigenous Australians not covered in this collection.

3.17 Regular GP or health service

Number and proportion of individuals who have a regular general practitioner (GP) or health service

Data sources

Data for this measure come from the ABS 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS).

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

Analyses

Self-reported data

Whether visited same doctor/health service

- In 2004–05, 91% of all Aboriginal and Torres Strait Islander people surveyed reported that they usually went to the same GP or medical service (Table 3.17.1).
- If they had a problem with their health, the majority (60%) of Indigenous Australians went to a doctor/GP outside of Aboriginal medical services (AMSs) and hospitals. The next highest proportion attended an Aboriginal medical service (30%). Approximately 7.0% of Indigenous people reported that they went to hospital for their regular health care.

Whether visited same doctor/health service by age and sex

- A slightly higher proportion of Indigenous Australians aged 0–14 years and 55 years and over reported they usually went to the same GP or medical service than those of other ages (93% and 94%, respectively) (Table 3.17.1; Figure 3.17.1).
- Similar proportions of Indigenous males and females reported they usually went to the same GP or medical service (90% and 91%, respectively) (Table 3.17.2).

- Approximately 3.0% of Indigenous males reported they did not seek health care if they had a problem with their health, compared with 1.0% of Indigenous females (Table 3.17.2).

Whether visited same doctor/health service by state/territory and remoteness

- A high proportion of Indigenous people used a doctor/GP (outside of AMSs and hospitals) for their regular health care across all jurisdictions, with the exception of the Northern Territory where only 14% reported using a doctor/GP, and 82% reported using an Aboriginal medical service. Nevertheless, significant differences existed between jurisdictions with regard to the type of service Indigenous people used for regular health care. The majority of Indigenous people (about two-thirds and over) in the Australian Capital Territory, South Australia, Victoria, New South Wales and Tasmania used a doctor (outside of AMSs and hospitals) for their regular health care (Table 3.17.3).
- A higher proportion of Indigenous persons used hospitals for regular health care in Queensland and Western Australia (12% and 14%, respectively) compared with other jurisdictions (Table 3.17.3).
- The proportion of Indigenous Australians using Aboriginal medical services for their regular health care increased with remoteness from 15% in *Major cities* to 76% in *Very remote* areas. The proportion of Indigenous Australians using a doctor/GP (outside of AMSs and hospitals) for their regular health care decreased with remoteness from 80% in *Major cities* and *Inner regional* areas to 6% in *Very remote* areas. Hospital use, however, was higher in *Remote* and *Very remote* areas (Table 3.17.4; Figure 3.17.2).

Figure 3.17.2: Whether Indigenous Australians usually go to the same GP/medical service, by remoteness, 2004–05

Whether visited same doctor/health service by selected population and health characteristics

- The proportion of Indigenous Australians who reported they usually went to the same GP or medical service was similar irrespective of language spoken at home or household income but was slightly higher among those in the 5th quintile (highest relative advantage) of the Socioeconomic Indexes of Areas (SEIFA) index of disadvantage (95%), those in non-remote areas (92%) and those with private health cover (93%) (Table 3.17.5).
- The proportion of Indigenous Australians who reported they usually went to the same GP or medical service was similar (around 90%) for those with reported excellent/very good/good health and those with fair/poor health, and for those with any number of long-term conditions (Table 3.17.6).

Discrimination/treatment when visited doctor/health service

- Indigenous people who usually went to the same GP or medical service were more likely to report that they were treated the same as non-Indigenous people when seeking health care over the last 12 months (78%) than those without a usual GP or medical service (70%). A similar proportion reported that they were treated worse (4%) or better (5%) than non-Indigenous people (Table 3.17.7).
- Sixteen per cent of Indigenous Australians reported that they felt they were treated badly because they were Indigenous.
- Of the people who reported that they felt they were treated badly because they were Indigenous, the majority felt angry (68%). Others reported feeling sad (26%), sorry for the person who treated them badly (32%), ashamed or worried about it (16%) or sick (12%).
- Of the people who reported that they felt they were treated badly because they were Aboriginal or Torres Strait Islander, 38% talked to family or friends about it, 34% reported that they tried to avoid the person/situation, and 27% just forgot about it.

Data quality issues

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It has therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in Major cities and Inner and outer regional and Remote and very remote areas, but very remote areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 National Health Survey.

In remote communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

Doctor/health service

The NATSIHS does not separately identify whether persons would go to this doctor/health service if they are sick or need advice about their health; if they had new health problems; if they needed preventative health care; or if they needed referrals. In the United States, persons are determined to have a usual primary care provider if they reported that they would usually go the same health professional for all four of these situations.

List of tables

List of figures

3.18 Care planning for chronic diseases

The use of care planning for the management of chronic disease among the Aboriginal and Torres Strait Islander population.

Data sources

Data on care planning come from the Medicare database, the Healthy for Life (HfL) data collection, the 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS), and the OATSIH Services Reporting (OSR) data collection.

Note that these data sources only provide part of the picture of the use of care planning for the management of chronic disease among the Indigenous population. Data on care-planning Medicare items will provide a more complete picture of care planning once the voluntary Indigenous identifier is more complete.

Medicare Database

Medicare enrolment application forms are lodged by persons wishing to enrol with Medicare at Medicare offices in each state/territory or by mail. Information from these forms is entered directly into the Medicare database, which is held by the Department of Health and Ageing (DoHA).

In November 2002, the ABS standard question on Indigenous identification was included on this form. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete.

As at 1 May 2012, 339,310 Indigenous Australians were enrolled on the VII database. This represents 59% of the estimated total Indigenous population (AHMAC 2012).

Medicare data presented in this report have been adjusted for under-identification. There are a number of caveats to the VII adjustment methodology, including that as the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could therefore be biases in the data that are not addressed by the adjustment methodology.

Healthy for Life

The Healthy for Life (HfL) program is an ongoing program funded by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) of the Australian Government Department of Health and Ageing (DoHA). The program aims to improve the capacity and performance of primary health-care services to deliver high-quality maternal, children’s and chronic disease care to Aboriginal and Torres Strait Islander people. This is carried out through population health approaches using best-practice and quality improvement principles.

Services participating in the HfL program are required to submit de-identified, aggregate service data for 11 essential indicators. These indicators cover maternal health, child health and chronic disease care on a regular basis (6 and 12 months), as well as information about the characteristics of their service and organisational infrastructure.

The Commonwealth and the AIHW are working with the states and territories to develop a national Key Performance Indicator (KPI) framework for Indigenous primary health care services. The new National KPIs will replace the *Healthy for Life* program Essential Indicators and cover maternal and child health and chronic disease management. The AIHW is leading the development and refinement of the indicators, data standards and analyses and reporting back to services. The national KPI data collection will be implemented in three stages, with rollout in 2012 and 2013.

National Aboriginal and Torres Strait Islander Health Survey

The 2004–05 National Aboriginal and Torres Strait Islander Health Survey (NATSIHS) collected information from 10,439 Indigenous Australians of all ages. This sample was considerably larger than the supplementary Indigenous samples in the 1995 and 2001 National Health Surveys. The survey was conducted in remote and non-remote areas of Australia and collected a range of information from Indigenous Australians. This included information on health-related actions, health risk factors, health status, socioeconomic circumstances and women's health. The survey provides comparisons over time in the health of Indigenous Australians. Selected non-Indigenous comparisons are available through the 2004–05 National Health Survey (NHS).

It is planned to repeat the NATSIHS at 6-yearly intervals, with the next survey to be conducted during 2012–13 as part of the Australian Health Survey (will be called the Australian Aboriginal and Torres Strait Islander Health Survey (ATSIHS)).

OATSIH Services Reporting data collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Analyses

MBS services claimed

Chronic disease management plans

From 1 July 2005, the Australian Government introduced chronic disease management Medicare items, including MBS items 721 and 723.

General Practitioner Management Plan (MBS item 721)

General Practitioner Management Plans (GPMPs) are for patients with a chronic or terminal medical condition who will benefit from a structured approach to management of their care needs. A rebate can be claimed once the patient's GP has prepared GPMP. The recommended frequency of GPMPs is once every 2 years. The GP may be assisted by their practice nurse, Aboriginal health worker or other health professional in the GP's medical practice or health service. The service must include a personal attendance by the GP with the patient.

Team Care Arrangement (MBS item 723)

Chronic disease management plans Team Care Arrangement (TCA) provide a rebate for a GP to coordinate the preparation of TCAs for a patient with a chronic or terminal medical condition who also requires ongoing care from a multidisciplinary team of at least three health or care providers. The recommended frequency is once every 2 years, supported by regular review services.

- Over the period 2009–10 to 2010–11 there has been an increase in the number of GP management plans (GPMP) and team care arrangements (TCA) claimed by Indigenous Australians (from 23,927 to 32,717 and from 18,680 to 26,525, respectively) (Table 3.18.1).
- After adjusting for differences in age structures between the two populations, Indigenous Australians received more claimed GPMPs than non-Indigenous Australians in 2010–11 (102 per 1,000 compared with 55 per 1,000) (Table 3.18.1).

Table 3.18.1: MBS services GPMP and TCA, by Indigenous status, Australia, 2009–10 and 2010–11

	Indigenous		Non-Indigenous	
	2009–10	**2010–11**	**2009–10**	**2010–11**
	Number of services			
GPMP	23,927	32,717	1,088,272	1,279,133
TCA	18,680	26,525	867,164	1,049,205
	Age standardised services per 1,000 population			
GPMP	75.6	102.0	46.7	55.0
TCA	59.7	83.0	37.2	45.0

Note: Data are adjusted for Indigenous under-identification.

Healthy for Life data

Chronic disease management plans

General Practitioner Management Plan (MBS item 721)

The proportion of Indigenous regular clients of Healthy for Life services aged 15 years and over with Type II diabetes and coronary heart disease who had a GPMP for the reporting period at 30 June 2010 is shown in Tables 3.18.2 and 3.18.3.

A number of services prepare GPMPs that do not meet the requirements of a complete MBS Item 721 GPMP, because these services do not have a GP. These GPMPs are referred to as 'Alternative GPMPs'. The purpose of this is to allow those services that are preparing Alternative GPMPs to report the data.

- Of the 11,928 Indigenous adults with Type II diabetes who are regular clients of the HfL services, 3,112 (26%) were managed under a GPMP (MBS item 721) (Table 3.18.2).
- *Inner regional* services had the highest proportion of Indigenous regular clients with Type II diabetes who were managed under a GPMP (37%) while the proportion was lowest in *Major cities* (17%).
- Of the 3,668 Indigenous regular clients with coronary heart disease, 1,062 (29%) were managed under a GPMP (Table 3.18.3).
- Services in *Remote*, *Very remote* and *Inner regional* areas had the highest proportion of Indigenous regular clients with coronary heart disease who were managed under a GPMP (ranging from 34% to 36% in these region) while the proportion was lowest in *Major cities* (17%).

Table 3.18.2: Number and proportion of Indigenous regular clients with Type II diabetes[(a)] who had a current GPMP, by remoteness, at 30 June 2010

	Major cities		Inner regional		Outer regional		Remote		Very remote		Total	
Type of GPMP	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**
MBS GPMP	16.7	360/2,158	36.6	539/1,474	23.9	844/3,526	28.7	766/2,673	28.8	603/2,097	26.1	3,112/11,928

(a) Indigenous regular clients aged 15 years and over.

(b) N (numerator) is the number of Indigenous regular clients with Type II diabetes who had a current GPMP. D (denominator) is the total number of Indigenous regular clients with Type II diabetes.

Notes

1. Valid data for this indicator were provided by 69 services (6 in major cities of Australia, 16in inner regional Australia, 22 in outer regional Australia, 12 in remote Australia and 13 in very remote Australia).
2. Services used their own definition of regular client.

Source: AIHW, Healthy for Life data collection.

Table 3.18.3: Number and proportion of Indigenous regular clients with coronary heart disease[(a)] who had a current GPMP by type of GPMP and remoteness, at 30 June 2010

	Major cities		Inner regional		Outer regional		Remote		Very remote		Total	
Type of GPMP	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**	**%**	**N/D[(b)]**
MBS and/or Alternative GPMP with all mandatory items[(c)]	17.1	155	32.2	207	30.0	332	35.3	241	35.6	119	28.7	1,054
Alternative GPMP without all mandatory items	0.0	0	1.2	8	0.0	0	0.0	0	0.0	0	0.2	8
Total GPMPs[(c)]	**17.1**	**155/904**	**33.5**	**215/642**	**30.0**	**332/1,105**	**35.3**	**241/683**	**35.6**	**119/334**	**29.0**	**1,062/3,668**

(a) Indigenous regular clients aged 15 years and over.

(b) N (numerator) is the number of Indigenous regular clients with Type II diabetes who had a current GPMP. D (denominator) is the total number of Indigenous regular clients with Type II diabetes.

(c) In a small number of services there is likely to be double counting of clients, as clients are reported to have had both an MBS and Alternative GPMP.

Notes

1. Valid data for this indicator were provided by 69 services (6 in major cities of Australia, 16 in inner regional Australia, 22 in outer regional Australia, 12 in remote Australia and 13 in very remote Australia).
2. Services used their own definition of regular client.

Team Care Arrangement (MBS item 723)

For Type II diabetes, valid data were provided by 49, 50, 56 and 65 services funded through the HfL program, for the reporting periods ending in June 2007, June 2008 and June 2009, respectively. For coronary heart disease, valid data were provided by 49, 49, 56 and 65 services, for these reporting periods. The number and proportion of Indigenous regular clients of these services with a chronic disease who have a current MBS item 723 TCA, by type of chronic disease, is shown in Table 3.18.4.

- Between 2007 and 2010 there was a substantial increase in the proportion of Indigenous regular clients with Type II diabetes or coronary heart disease who had a current TCA (MBS item 723). At 30 June 2007, 4% of clients with type II diabetes and 3% with coronary heart disease had a current TCA. This increased to 23% for each type of disease at 30 June 2010 (Table 3.18.4).

Table 3.18.4: Number and proportion of Indigenous regular clients[(a)] with a chronic disease[(b)] who had a current TCA (MBS item 723), by type of chronic disease, at 30 June 2007 to 30 June 2010

	Jun–07		Jun–08		Jun–09		Jun–10	
Type of chronic disease	**%**	**N/D[(c)]**	**%**	**N/D[(c)]**	**%**	**N/D[(c)]**	**%**	**N/D[(c)]**
Type II diabetes	3.8	85/2,252	13.1	931/7,084	19.2	1,520/7,905	22.8	2,566/11,230
Coronary heart disease	2.9	28/956	13.2	284/2,148	18.1	415/2,294	22.6	792/3,510

(a) Indigenous regular clients aged 15 years and over.

(b) Chronic diseases include Type II diabetes and coronary heart disease.

(c) N (numerator) is the number of Indigenous regular clients who had a current TCA. D (denominator) is the total number of Indigenous regular clients with a chronic disease.

Note: For Type II diabetes, valid data were provided by 49, 50, 56 and 65 services, for the reporting periods ending in June 2007, June 2008, June 2009 and June 2010 respectively. For coronary heart disease, valid data were provided by 49, 49, 56 and 65 services, for the reporting periods ending in June 2007, June 2008, June 2009 and June 2010 respectively.

Source: AIHW Healthy for Life data collection.

Health service linkages

- From the reporting period ending June 2008 to that ending June 2010 there was an increase from 63% to 77% of services reporting they had hospital admission communication for clients with chronic disease. Over the same period, the proportion of services reporting they had hospital discharge communication for their clients with chronic disease increased from 72% to 77%, and the proportion of those reporting care provided in residential aged care services for clients with chronic disease increased from 40% to 53% (Table 3.18.5).

Table 3.18.5: Proportion of services funded through the Healthy for Life Program that had care planning and health service linkages for their clients with chronic disease, reporting periods ending 30 June 2008, 30 June 2009 and 30 June 2010

HfL services had strategies for chronic disease management[(a)] for their clients with chronic disease that included:	Jun–08			Jun–09			Jun–10		
	% Yes	% No	% No response	% Yes	% No	% No response	% Yes	% No	% No response
Health service linkages									
Hospital admission communication	62.7	25.4	11.9	70.3	14.9	14.9	77.2	12.7	10.1
Hospital discharge communication	71.6	16.4	11.9	71.6	13.5	14.9	77.2	12.7	10.1
Care provided in residential aged care services	40.3	49.3	10.4	43.2	41.9	14.9	53.2	36.7	10.1

(a) 'Management' includes health promotion, prevention of complications, clinical care and advocacy.

NATSIHS data

Asthma action plans

The 2004–05 NATSIHS collected self-reported data on the number of Indigenous and non-Indigenous Australians in non-remote areas with long-term health conditions, such as asthma, and whether the person has a written action plan. Data on asthma action plans by Indigenous status, age and state/territory are presented below.

- In 2004–05, approximately 17% of Indigenous Australians living in non-remote areas reported asthma as a long-term condition. After adjusting for differences in age distribution, Indigenous Australians were almost twice as likely as non-Indigenous Australians to report asthma as a long-term condition (Table 3.18.6).
- In 2004–05, similar proportions of Indigenous and non-Indigenous Australians with asthma living in non-remote areas reported having written asthma action plans (25% and 22%, respectively) (Table 3.18.6).
- Indigenous Australians aged 0–4 and those aged 55 years and over were the most likely to have a written asthma action plan (44% and 35%, respectively).
- New South Wales had the highest (31%), and Western Australia the lowest (17%), proportion of Indigenous Australians reporting having a written asthma action plan (Table 3.18.7).
- In 2004–05, the majority of Indigenous and non-Indigenous Australians with written asthma action plans reported the source of their plan to be a doctor (91% and 95%, respectively) (Table 3.18.8).

Table 3.18.6: Whether persons in non-remote areas have a written asthma action plan, by Indigenous status and age group, 2004–05

OATSIH Services Reporting (OSR) data

Care planning provided by Indigenous primary health care services

Data presented below are from the 2010–11 OSR collection.

- In 2010–11, 92% of Indigenous primary health-care services provided care planning, 74% reported that discharge planning was well coordinated between the hospital and the service, and 80% of services provided or facilitated shared care arrangements for the management of people with chronic conditions (Table 3.18.9, Figure 3.18.1).

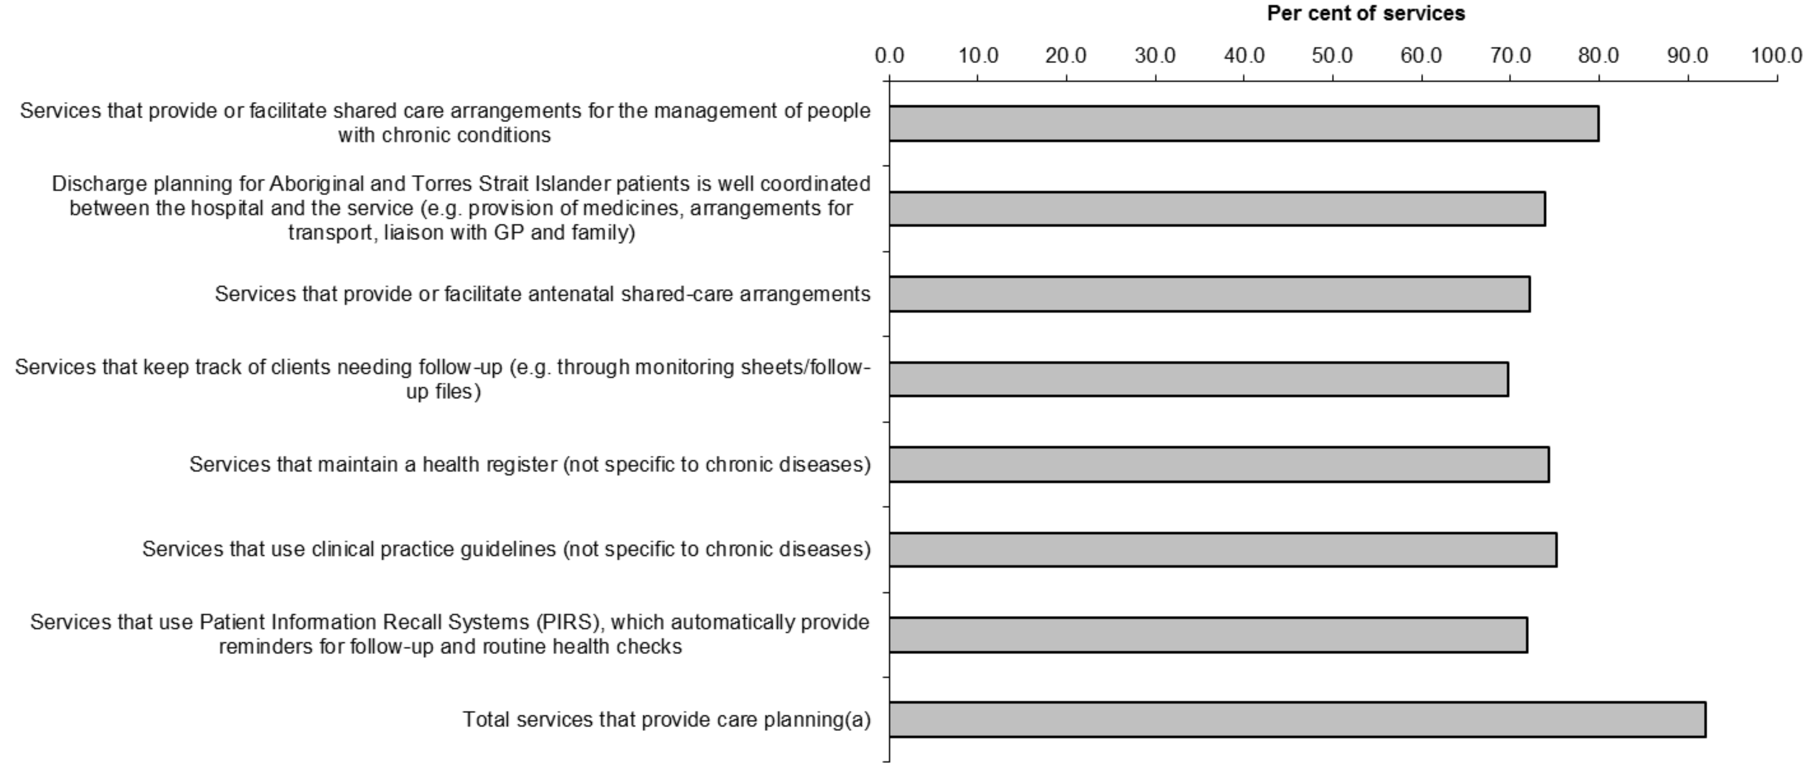
Table 3.18.9: Number and proportion of respondent Aboriginal and Torres Strait Islander primary health-care services that provide care planning, 2010–11

	Number	Per cent
Services that provide or facilitate shared care arrangements for the management of people with chronic conditions	187	79.9
Discharge planning for Aboriginal and Torres Strait Islander patients is well coordinated between the hospital and the service (e.g. provision of medicines, arrangements for transport, liaison with GP and family)	173	73.9
Services that provide or facilitate antenatal shared-care arrangements	169	72.2
Services that keep track of clients needing follow-up (e.g. through monitoring sheets/follow-up files)	163	69.7
Services that maintain a health register (not specific to chronic diseases)	174	74.4
Services that use clinical practice guidelines (not specific to chronic diseases)	176	75.2
Services that use Patient Information Recall Systems (PIRS), which automatically provide reminders for follow-up and routine health checks	169	71.9
Total services that provide care planning[(a)]	***216***	***91.9***
Total services	**235**	**100.0**

(a) Total services that provide at least one of the activities listed.

Note: Two hundred and thirty-four of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data about health related activities provided by the service for 2010–11. Percentages for the first 6 categories are calculated as a proportion of these 234 services. However, all of the 235 services provided valid data for using computers for 2010–11. The percentage for the use of PIRS is calculated as a proportion of these 235 services. The categories are from different questions so the denominator is not consistent.

Source: AIHW OSR data collection.



(a) Total includes services that provide at least one of the activities listed

Note: Two hundred and one of the 205 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data about health related activities provided by the service. The percentages for first six categories in the table above are calculated as a proportion of these 201 services. However, more services (203) provided valid data about computer use. Thus the last two percentages are calculated as a proportion of 203 services. Because those categories are from two different questions, the denominator is not consistent.

Source: AIHW OSR data collection.

Figure 3.18.1: Proportion of respondent Aboriginal and Torres Strait Islander primary health-care services that provide care planning, 2010–11

Data quality issues

Medicare data

MBS items

The MBS items included in this measure have been introduced over the last few years with the child health check item commencing in May 2006. The take-up of new MBS items is influenced by the speed at which practitioners and the population become aware of the new items and how to use them. Also take-up can be influenced by administrative processes and the time taken to change computer systems to incorporate these new items. Analysis of monthly statistics on Items 704 and 706 suggest that it took several years for these statistics to stabilise into a fairly regular pattern. Item 710 was introduced in May 2004 and monthly statistics have become relatively stable within 12 months.

Standard Indigenous status question

In November 2002, the ABS standard question on Indigenous identification was included on Medicare enrolment forms. The question is asked in relation to the cardholder and any other family member named on the card. Responding to the question is voluntary and there is an explanation of the reasons for the question and the use of the data included on the form. This is referred to as the Voluntary Indigenous Identifier.

Under-identification

Because the Voluntary Indigenous Identifier was only introduced recently, the coverage of Aboriginal and Torres Strait Islander Australians in this database is not complete. There were around 339,310 people who had identified as Aboriginal and/or Torres Strait Islander in this database at May 2012; around 59% of the estimated Aboriginal and Torres Strait Islander population (AHMAC 2012). There has been a rapid expansion in the number of enrolees who identified as Aboriginal and/or Torres Strait Islander, from 47,200 people in August 2004.

Readers should note the following caveats to the Medicare voluntary Indigenous Identifier (VII) adjustment methodology:

- Estimates generated by the adjustment methodology for a given period will vary according to the point in time at which they are calculated, as the adjustment factors will be updated regularly to account for the ongoing change in the population coverage of the VII sample.
- There are inherent uncertainties in the current ABS Indigenous population estimates, and they are therefore described by the ABS as 'experimental estimates and projections'. The ABS Indigenous population estimates after 2006–07 are experimental projections, based on a number of assumptions about future levels of fertility, mortality and migration. The projections are not predictions or forecasts, but are illustrations of the growth and change in population that would occur if these assumptions were to prevail over the projection period. There can be no certainty that any particular outcome will be realised, or that future outcomes will necessarily fall within the projected ranges.
- The propensity to identify as Aboriginal and/or Torres Strait Islander varies according to the motivations of the individual and the perceived uses of the data in question. For example, it is possible that there are some Aboriginal and Torres Strait Islander people who are registered with the VII but who do not identify as Indigenous for the purposes of the Census, or vice versa.
- In some areas, particularly remote and very remote areas, there is a portion of the Indigenous population that does not ever use the Medicare system. It is therefore

possible that the adjustment methodology could overestimate Medicare use by the Indigenous population.

- As the VII sample is generated voluntarily, it is not truly random and cannot be perfectly representative of the Indigenous population until full coverage is achieved. There could be biases in the data that are not addressed by the adjustment methodology.

Healthy for Life data

For the July 2009 to June 2010 reporting period, 79 services submitted data as part of the Healthy for Life (HfL) Program.

Services started submitting their data through an electronic interface (OSCAR) for the February 2008 reporting period. This has improved the quality of data submitted.

Not all of the services were able to provide data for all of the essential indicators and service profile questions included in the HfL data collection. The number of services that were able to provide data varies across the qualitative and quantitative indicators.

There has been an upward trend in the proportion of services that reported on each of the indicators over time, particularly compared with the first reporting period ending June 2007. All of the services reporting provided data for all of the EIs in the period ending December 2009. This proportion decreased slightly in the current reporting period ending June 2010. This may be because services need to report against fewer EIs and do not need to provide most qualitative data in periods ending in December, unlike in annual reporting periods ending in June. The current period had higher proportions of services that reported against most EIs than the previous annual collection period ending June 2009.

In general, the data quality improved noticeably between the period ending June 2008 and the period ending June 2009. The overall level of data quality remained similar in the current period, though there was a different pattern of data quality issues.

The current period ending June 2010 had a different distribution of data quality issues than the previous period. No services had inconsistencies between related indicators, however the number of services with missing data and data out of the expected range increased. The latter might be due to more stringent data checking procedures employed by the AIHW during the current period.

National Aboriginal and Torres Strait Islander Health Survey (NATSIHS)

The NATSIHS uses the standard Indigenous status question. The 2004–05 NATSIHS sample was specifically designed to select a representative sample of Aboriginal and Torres Strait Islander Australians. It therefore overcomes the problem inherent in most national surveys with small and unrepresentative Indigenous samples. As with other surveys, the NATSIHS is subject to sampling and non-sampling errors. Calculations of standard errors and significance testing help to identify the accuracy of the estimates and differences.

Information recorded in this survey is essentially 'as reported' by respondents. The ABS makes every effort to collect accurate information from respondents, particularly through careful questionnaire design, pre-testing of questionnaires, use of trained interviewers and assistance from Indigenous facilitators. Nevertheless, some responses may be affected by imperfect recall or individual interpretation of survey questions.

Non-Indigenous comparisons are available through the National Health Survey (NHS). The NHS was conducted in *Major cities*, *Inner and outer regional* areas and *Remote and very remote* areas, but *Very remote* areas were excluded from the sample. Time series comparisons are available through the 1995 and 2001 NHS.

In *Remote and very remote* communities there were some modifications to the NATSIHS content in order to accommodate language and cultural appropriateness in traditional communities and help respondents understand the concepts. Some questions were excluded and some reworded. Also, paper forms were used in communities in remote areas and computer-assisted interview (CAI) instruments were used in non-remote areas. The CAI process included built-in edit checks and sequencing.

Further information on NATSIHS data quality issues can be found in the NATSIHS 2004–05 publication (ABS 2006).

OATSIH Services Reporting (OSR)

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012).

3.19 Accreditation

The proportion of:

- **accredited public hospital Aboriginal and Torres Strait Islander separations and patient days as a percentage of all Aboriginal and Torres Strait Islander separations and patient days in public hospitals**
- **accredited general medical practice service establishments by proportion of Indigenous populations in Divisions of General Practice**

Data sources

Data for this measure come from the National Hospital Morbidity database, the AIHW National Public Hospitals Establishment Database, the Australian General Practice Accreditation Limited (AGPAL) and the General Practice Accreditation Plus (GPA+), the OATSIH Services Reporting (OSR) and the Healthy for Life Program.

National Hospital Morbidity Database

The National Hospital Morbidity Database is a compilation of episode-level records from admitted patient morbidity data collection systems in Australian hospitals in each state and territory. Information on the characteristics, diagnoses and care of admitted patients in public and private hospitals is provided annually to the AIHW by state and territory health departments.

Hospitalisation data are presented for the 2-year period from July 2008 to June 2010. An aggregate of 2 years of data has been used, because the number of hospitalisations for some conditions is likely to be small for a single year.

Hospital records are for ‘separations’ and not individuals, and as there can be multiple admissions for the same individual, hospital separation rates do not usually reflect the incidence or prevalence of the disease or condition in question. For example, it is not possible to identify whether one patient was admitted 5 times or five patients were admitted once. People who receive treatment at hospital but are not admitted are not counted in hospital records. Hospital separation data are also affected by variations in admission practices, and the availability of and access to hospital and non-hospital services.

Care types 7.3, 9 and 10 (Newborn – unqualified days only; organ procurement; hospital border) have been excluded from analysis.

Data are presented for the six jurisdictions that the AIHW has assessed as having adequate identification of Indigenous hospitalisations in 2006–08—New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory (public hospitals only). These six jurisdictions represent approximately 96% of the Indigenous population of Australia. National totals include separations for people resident in these six jurisdictions only and are not necessarily representative of the jurisdictions not included. Indigenous status data are reported for Tasmania and the Australian Capital Territory (public hospitals only) with caveats until further audits of the quality of data in these jurisdictions are completed. Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Data are presented by state/territory of usual residence of the patient.

The following caveats have been recommended for analysis of hospitalisation data from selected jurisdictions (AIHW 2010):

- Interpretation of results should take into account the relative quality of the data from the jurisdictions included (currently a small degree of Indigenous under-identification in data from New South Wales and South Australia, and relatively marked Indigenous under-identification in data from Queensland and Victoria).
- Interpretation of time series analysis should take into account the possible contribution of changes over time in ascertainment of Indigenous status. This will be reflected in Indigenous patient changes in hospitalisation rates for Indigenous people.

AIHW National Pubic Hospitals Establishment Database

The AIHW National Public Hospitals Establishment Database holds establishment-level data for public hospitals within the jurisdiction of the state and territory health authorities. Private hospitals and public hospitals not administered by the state and territory health authorities are not included. Information is provided annually to the AIHW by state and territory health departments.

Data are presented for all jurisdictions and by state/territory of usual residence of the patient.

AGPAL and GPA Accreditation Plus

Australian General Practice Accreditation Limited (AGPAL) and GPA Accreditation Plus (GPA+) are the two general practice accreditation providers operating in Australia. All practices accredited with AGPAL and GPA+ are assessed against the Royal Australian College of General Practitioners' standards. General practice accreditation in Australia ensures practices are eligible to participate in the Practice Incentives Program (PIP) – a blended payment administered by Medicare Australia on behalf of the Department of Health and Ageing (DoHA).

OATSIH Services Reporting data collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in

earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Healthy for Life

The Healthy for Life (HfL) program is an ongoing program funded by the Office for Aboriginal and Torres Strait Islander Health (OATSIH) of the Australian Government Department of Health and Ageing (DoHA). The program aims to improve the capacity and performance of primary health-care services to deliver high-quality maternal, children's and chronic disease care to Aboriginal and Torres Strait Islander people. This is carried out through population health approaches using best-practice and quality improvement principles.

Services participating in the HfL program are required to submit de-identified, aggregate service data for 11 essential indicators. These indicators cover maternal health, child health and chronic disease care on a regular basis (6 and 12 months), as well as information about the characteristics of their service and organisational infrastructure.

The Commonwealth and the AIHW are working with the States and Territories to develop a national Key Performance Indicator (KPI) framework for Indigenous primary health care services. The new National KPIs will replace the *Healthy for Life* program Essential Indicators and cover maternal and child health and chronic disease management. The AIHW is leading the development and refinement of the indicators, data standards and analyses and reporting back to services. The national KPI data collection will be implemented in three stages, with rollout in 2012 and 2013.

Analyses

Accreditation is generally a voluntary process by which a recognised body—usually a non-government organisation—assesses and recognises that a health-care organisation meets applicable quality standards. The two pre-conditions for accreditation are an explicit definition of quality (that is, standards) and an independent review process aimed at identifying whether practices meet the quality standards (ACHCS 2005). Accreditation provides public recognition that a health-care organisation has undertaken a process to ensure it meets the requirements of national health-care standards. All health-care organisations—whether they are in the public or private sector, local community-based care facilities or tertiary level providers— can undergo accreditation.

Public hospital accreditation

Data on the proportion of hospitalisations in accredited hospitals for Indigenous and non-Indigenous Australians in all states and territories over the 2-year period from July 2008 to June 2010 are presented in Tables 3.19.1–3.

- Over this period, there were 531,050 hospitalisations of Indigenous Australians in accredited public hospitals. This was 96% of all public hospitalisations of Indigenous

Australians. Over the same period, 97% of hospitalisations of non-Indigenous Australians were in accredited public hospitals (Table 3.19.1).

Hospital accreditation by state/territory and remoteness

- The proportion of hospitalisations of Indigenous Australians that were in accredited hospitals ranged from 85% in New South Wales to 100% in Victoria, the Australian Capital Territory and the Northern Territory (Table 3.19.1).
- Over the 2-year period from July 2008 to June 2010, about 95% of days spent by Indigenous patients and 96% of days spent by non-Indigenous Australians in hospital were in accredited hospitals (Table 3.19.2).
- The proportion of hospitalisations of Indigenous Australians that were in accredited hospitals was highest among those in regional areas (99% in *Inner regional* and 96% in *Outer regional*) and lowest among those in *Very remote* areas (90%). For non-Indigenous hospitalisations, the proportions ranged from 88% in *Remote areas* to 99% in *Inner regional* areas (Table 3.19.3).

Hospital accreditation by hospital category

- In all jurisdictions, all hospitalisations of Indigenous and non-Indigenous Australians in specialist women and children's hospitals, large regional and remote hospitals and medium major cities and regional group 1 hospitals, were in accredited hospitals (Table 3.19.4).

- Between 63% and 91% of hospitalisations of Indigenous Australians and 87% and 92% of hospitalisations of non-Indigenous Australians in small hospitals were in accredited hospitals.
- Around two-thirds (68%) of Indigenous hospitalisations in multi-purpose service hospitals were in accredited hospitals. This compared with 89% of non-Indigenous hospitalisations.

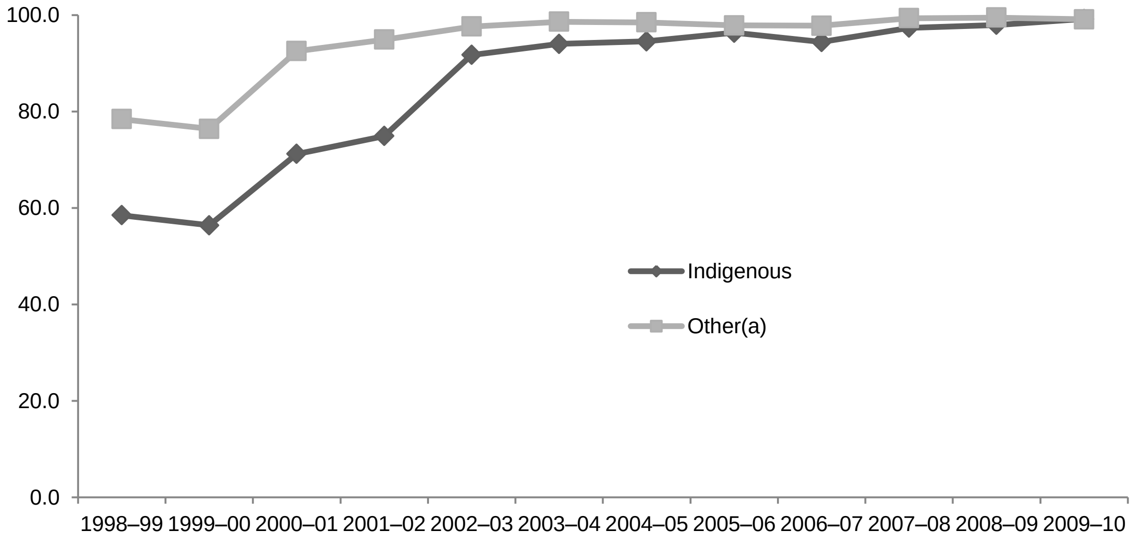
Time series analyses

Time series data are presented for the four jurisdictions that have been assessed as having adequate identification of Indigenous hospitalisations from 1998–99 onwards—Queensland, Western Australia, South Australia and the Northern Territory. These four jurisdictions represent approximately 60% of the Indigenous Australian population.

- Between 1998–99 and 2009–10 in these four jurisdictions combined, there were increases in the proportion of hospitalisations of Indigenous and other Australians in accredited hospitals (from 59% to 99% for Indigenous hospitalisations and from 78% to 99% for other hospitalisations) (Figure 3.19.1; Table 3.19.5).
- Although the difference between the proportion of Indigenous and non-Indigenous separations in accredited hospitals appears to decline between 1998–99 and 2009–10, this may be the result of more hospitals in rural and remote areas obtaining accreditation in recent years. A higher proportion of Indigenous Australians than non-Indigenous Australians were hospitalised in these areas (Table 3.19.5).



(a) 'Other' includes hospitalisations for non-Indigenous people and those for whom Indigenous status was not stated.

Source: AIHW analysis of National Hospital Morbidity Database and National Public Hospitals Establishment Database.

Figure 3.19.1: Proportion of hospitalisations in accredited public hospitals, by Indigenous status, Qld, WA, SA and NT combined, 1998–99 to 2009–10

Table 3.19.5: Proportion of hospitalisations in accredited public hospitals, by Indigenous status, Qld, WA, SA and NT combined, 1998–99 to 2009–10(a)(b)(c)(d)

	Indigenous	Other(e)	Rate ratio(f)	Rate difference(g)
1998–99	58.5	78.4	0.7	–19.9
1999–00	56.4	76.4	0.7	–20.0
2000–01	71.2	92.5	0.8	–21.3
2001–02	74.9	94.9	0.8	–20.0
2002–03	91.7	97.6	0.9	–5.9
2003–04	94.0	98.6	1.0	–4.6

General practice accreditation

Information on the accreditation of general practices is available from the Annual Survey of Divisions of General Practice and from the two registered providers of general practice accreditation in Australia—AGPAL and GPA+.

Table 3.19.6 and Figure 3.19.2 present data on the number and proportion of general practices accredited in Australia.

- In 2010–11, data from AGPAL and GPA+ estimated that there were 5,918 (71%) general practices accredited in Australia, and a further 2,429 practices registered but not yet accredited.
- Approximately 69% of general practices in areas where less than 1% of the population was Indigenous were accredited. Between 69% and 84% of general practices in areas where between 1 and 10% of the population were Indigenous were accredited. In areas

where more than 10% of the population were Indigenous, 61% of general practices were accredited (Table 3.19.6).

Table 3.19.6: Number of general practices accredited through AGPAL and GPA+, by proportion of the population that is Indigenous[(a)], 2010–11

Proportion of Indigenous[(a)]	Number of accredited	Per cent accredited	Registered but not yet accredited	Total number of accredited and registered practices
<1%	2,008	68.6	918	2,926
1–2%	1,875	69.1	839	2,714
2–3%	899	72.5	341	1,240
3–4%	411	79.0	109	520
4–10%	535	84.3	100	635
>10%	190	60.9	122	312
Total	**5,918**	**70.9**	**2,429**	**8,347**

(a) Aboriginal and Torres Strait Islander proportions are based on ABS population estimates used in the Annual Survey of Divisions of General Practice.

Notes

1. Includes one Division for which the proportion of the Indigenous population was not available.
2. There is double counting of some services where general practices reside on the border of two divisions. In that case two divisions may service the same practice.

Figure 3.19.2: Proportion of general practices accredited[(a)] by Divisions of General Practice, by proportion of the population that is Indigenous[(b)], 2010–11

Accreditation of Aboriginal and Torres Strait Islander primary health-care services

OATSIH recognises that there are several accreditation frameworks for clinical or other service delivery relevant to the Indigenous health sector. Work is currently underway to explore options for a streamlined and integrated approach to accreditation under multiple frameworks. Until the outcomes of this work are available, organisations will be supported to undertake clinical or other service delivery accreditation. For example, organisations with a GP will be supported to obtain accreditation against the Royal Australian College of General Practitioners (RACGP) standards for general practice. Other services may recognise an alternative accreditation framework that reflects their service delivery; for example, Quality Improvement Council (QIC) modules deal with services such as home-based care services, alcohol, tobacco and other drugs services, and mental health services. Organisations that obtain service delivery accreditation through a discrete framework will also be supported to work towards organisational accreditation through the accreditation frameworks of organisations such as the QIC or International Standards Organisation (ISO).

Reform in this area is likely to be led by the Australian Commission on Safety and Quality in Health Care, which is currently considering reforms to standards and accreditation in Australian health care. Part of this work includes the development of mandatory Australian health-care safety standards.

Information on the accreditation of Indigenous primary health-care services is available from the registered providers of general practice accreditation (AGPAL and GPA+); the QIC; the OSR data collection and from the AIHW HfL Data Collection. Note that there is great overlap in the services that are captured in each of these data sources.

OATSIH Services Reporting (OSR) data

Accreditation is an important part of quality improvement in primary health-care services. In 2010–11, 71% of all Indigenous primary health-care services (235) were accredited.

- In 2010–11, 82% of the 147 Indigenous primary health-care services that had a General Practitioner on staff reported being accredited, and 52% of the 88 Indigenous primary health-care services without a GP on staff reported being accredited (Table 3.19.7).
- Of all accredited services, 123 (74%) were accredited against the RACGP standards for accreditation only (which includes accreditation through AGPAL and GPA+), 47 (28%) were accredited against organisational standards (which includes QIC, ISO, etc) and 30 (18%) were accredited through another provider (AIHW 2012).
- Around half (52%) of the 88 Indigenous primary health-care services without a GP on staff reported being accredited (Table 3.1.8)— 11 (24%) of these were accredited against organisational standards (which includes QIC, ISO, etc) four (9%) were accredited against the RACGP standards and three (7%) were accredited through another provider (AIHW OSR data collection unpublished).

Table 3.19.7: Number and proportion of Aboriginal and Torres Strait Islander primary health-care services, by accreditation status, 2010–11

Accreditation status	Services with a GP	Services without a GP	Total accreditation
		Number of services	
Accredited	121	46	167
Not accredited	26	42	68
Total	**147**	**88**	**235**
		Proportion of services (%)	
Accredited	82.3	52.3	71.1
Not accredited	17.7	52.2	28.9

Healthy for Life Program

Information on the accreditation status of services funded through the HfL program is available from the AIHW Healthy for Life data collection.

- As at 30 June 2010, of the 79 services that were included in the Healthy for Life program and reported information on accreditation, almost two-thirds (66%) were accredited and 18% were undergoing accreditation. AGPAL was the most commonly used registered accreditation provider, with 36 services being accredited with this provider and 10 undergoing accreditation (Table 3.19.8).

Table 3.19.8: Number and proportion of services, by accreditation status, by recognised provider, at 30 June 2010

	Recognised provider

Data quality issues

National Hospital Morbidity Database

The scope of the NMDS is episodes of care for admitted patients in essentially all hospitals in Australia, including public and private acute and psychiatric hospitals, free-standing day hospital facilities, alcohol and drug treatment hospitals and dental hospitals. Hospitals operated by the Australian Defence Force, corrections authorities and in Australia's off-shore territories are not included. Hospitals specialising in ophthalmic aids and other specialised acute medical or surgical care are included. The NHMD does not include episodes of non-admitted patient care provided in outpatient clinics or emergency departments.

For 2009–10 almost all public hospitals provided data for the NHMD, with the exception of all separations for a mothercraft hospital in the Australian Capital Territory and about 2,400 separations for one public hospital in Western Australia. The majority of private hospitals provided data, with the exception of the private day hospital facilities in the Australian Capital Territory and the Northern Territory. In addition, Western Australia was not able to provide about 10,600 separations for one private hospital.

Separations

Data are a count of hospital separations (episodes of admitted patient care, which can be a total hospital stay or a portion of a hospital stay beginning or ending in a change of type of care) and not patients. Patients who separated from hospital more than once in the year will be counted more than once in the data set.

The number and pattern of hospitalisations can be affected by differing admission practices among the jurisdictions and from year to year, and differing levels and patterns of service delivery.

Separations with care types of *Newborn* episodes that did not include qualified days, and records for *Hospital boarders* and *Posthumous organ procurement* have been excluded as these activities are not considered to be admitted patient care.

Indigenous status question

Some jurisdictions have slightly different approaches to the collection and storage of the standard Indigenous status question and categories in their hospital collections.

Approximately 2% of hospital records have missing Indigenous status information.

Hospitalisations for which the Indigenous status of the patient was not reported are excluded from hospitalisations data for non-Indigenous Australians, apart from Western Australia where records with an unknown status are recorded as non-Indigenous.

Under-identification

The incompleteness of Indigenous identification means the number of hospital separations recorded as Indigenous is an underestimate of hospitalisations involving Aboriginal and Torres Strait Islander people. In 2007, the AIHW completed an assessment of the level of Indigenous under-identification in selected public hospitals in all states and territories. Results from this assessment indicate that New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory have adequate Indigenous identification (20% or less overall under-identification of Indigenous patients) in their hospital separations data.

It has therefore been recommended that reporting of Indigenous hospital separations data be limited to aggregated information from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory. Interpretation of results should take into account the relative quality of the data from the jurisdictions. The

proportion of the Indigenous population covered by these six jurisdictions is 96%. Tasmania and the Australian Capital Territory data are presented at the State/Territory level and should be used with caution, but they are not aggregated with the other 6 jurisdictions.

From the AIHW study, it was possible to produce correction factors for the level of Indigenous under-identification in hospital data for each jurisdiction and at the national level. Adjustments for Indigenous under-identification have been made at the national level for the total number of hospital separations using an adjustment factor of 89%. No adjustments for under-identification have been made at the state/territory level or principal diagnosis level.

The 2007 AIHW study indicated acceptable levels of Indigenous identification for all remoteness areas, ranging from 80% in *Major cities* to 97% in *Remote* and *Very remote* areas. The quality of data supports analyses for hospitalisations by remoteness areas at the national level only.

In 2011–12, the AIHW commenced another study to re-assess the level of under-identification in public hospitals data. All states and territories have participated in the study to assess improvements in data quality. A report on the findings is expected to be published in mid-2013 which will include new correction factors for the level of Indigenous under-identification in hospital separations data at the national, state/territory and remoteness levels.

Numerator and denominator

Rate and ratio calculations rely on good numerator and denominator data. There are changes in the completeness of identification of Indigenous people in hospital records. These may take place at different rates from changes in the identification of Indigenous people in other administrative collections and population censuses. Denominators used in this analysis are sourced from *Experimental estimates and projections: Aboriginal and Torres Strait Islander Australians 1991 to 2021* (ABS 2009).

AIHW National Public Hospitals Establishment Database

The AIHW National Public Hospitals Establishment Database is subject to the same data quality limitations as the AIHW National Hospital morbidity Database above.

AGPAL and GPA Accreditation Plus

There is double counting of some services where general practices reside on the border of two divisions. In such cases, two divisions may service the same practice. Data reported on practices accredited by the proportion Indigenous persons in the population are based on ABS population estimates used in the Annual Survey of Divisions of General Practice.

OATSIH Services Reporting (OSR)

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012).

Healthy for Life data

For the July 2009 to June 2010 reporting period, 79 services submitted data as part of the Healthy for Life (HfL) Program.

Services started submitting their data through an electronic interface (OSCAR) for the February 2008 reporting period. This has improved the quality of data submitted.
Not all of the services were able to provide data for all of the essential indicators and service profile questions included in the HfL data collection. The number of services that were able to provide data varies across the qualitative and quantitative indicators.

There has been an upward trend in the proportion of services that reported on each of the indicators over time, particularly compared with the first reporting period ending June 2007. All of the services reporting provided data for all of the EIs in the period ending December 2009. This proportion decreased slightly in the current reporting period ending June 2010. This may be because services need to report against fewer EIs and do not need to provide most qualitative data in periods ending in December, unlike in annual reporting periods ending in June. The current period had higher proportions of services that reported against most EIs than the previous annual collection period ending June 2009.

In general, the data quality improved noticeably between the period ending June 2008 and the period ending June 2009. The overall level of data quality remained similar in the current period, though there was a different pattern of data quality issues.

The current period ending June 2010 had a different distribution of data quality issues than the previous period. No services had inconsistencies between related indicators, however the number of services with missing data and data out of the expected range increased. The latter might be due to more stringent data checking procedures employed by the AIHW during the current period.

List of figures

3.20 Aboriginal and Torres Strait Islander people training for health-related disciplines

The proportion of Aboriginal and Torres Strait Islander Australians in tertiary education for health-related disciplines

Data sources

Data for this measure come from the Australian Government Department of Education, Employment and Workplace Relations (DEEWR) Higher Education Student Statistics Collection and the National Centre for Vocational Education Research (NCVER) National Vocational Education and Training (VET) Provider Collection.

DEEWR Higher Education Student Statistics Collection

The Australian Government Department of Education, Employment and Workplace Relations (DEEWR) is the responsible agency for the Higher Education Students Statistics Collection, which includes information from higher education institutions such as universities and colleges of advanced education. This data collection contains statistics relating to students enrolled in higher education courses between 1 January and 31 December of each year in each Australian higher education provider.

National Vocational Education and Training (VET) Provider Collection

The National Centre for Vocational Education Research is Australia's main provider of vocational education and training (VET) sector research and statistics. VET is a national system designed to give workers the skills for particular occupations and industries. The VET sector includes providers that receive public VET funding, such as technical and further education organisations, higher education institutions, other government providers (for example, agricultural colleges), community education providers, government-funded private registered training organisations, schools funded through government allocations for VET, and all other Commonwealth and state recurrent and specific-purpose funded VET, regardless of the location of the training organisation.

Analyses

Higher education sector enrolments

Data on Indigenous student enrolments in higher education university health-related courses are available from the DEEWR Higher Education Students Statistics Collection. Data for 2010 by age group is presented in Table 3.20.1 and Figure 3.20.1.

- In 2010 there were 1,766 Indigenous students aged 15 years and over enrolled in selected higher education health-related courses. This was equivalent to a rate of 48 enrolments per 10,000 population. There were 107,481 other Australian students aged 15 years and over who were enrolled in health-related higher education courses in 2010 which was a rate of 62 enrolments per 10,000 population (Table 3.20.1).

- Indigenous students enrolled in health-related courses were generally older than other Australian students. Indigenous students had slightly higher rates of enrolment for the 35–44, 45–54 and 55 and over age groups, a similar rate of enrolment for the 25–34 year age group, and a much lower rate for those aged 15–24 (Figure 3.20.1).

Table 3.20.1: Higher education university health-related course enrolments by age group and Indigenous status, 2010

Figure 3.20.1: Higher education university health-related course enrolments by Indigenous status and age group, per 10,000 population, 2010

Data on the number of Indigenous students in university health-related courses by type of course are available from the Higher Education Student Statistics Collection. Data for the number of Indigenous students in university health-related courses in 2010 are presented in Table 3.20.2 and by state and territory in Table 3.20.3.

- In 2010, 1,415 Indigenous undergraduate domestic students were studying university health-related courses, which was equal to a rate of 39 per 10,000 population. This compares with a rate of 44 per 10,000 for other undergraduate domestic students (Table 3.20.2).
- The most common health-related course for both Indigenous Australian and other Australian students was nursing (21 per 10,000), followed by public health for Indigenous students (9 per 10,000) and medical studies and rehabilitation therapies for other students (8 and 7 per 10,000, respectively).
- The Northern Territory had the highest proportion of Indigenous students enrolled in health-related undergraduate courses (10% of all domestic undergraduate students), followed by New South Wales and Queensland (2% for each jurisdiction) (Table 3.20.3).

Table 3.20.2: Undergraduate domestic students[(a)] enrolled in health-related courses[(b)], Indigenous and Other students, 2010

	Indigenous		Other students		
Course	**Number**	**Rate(per 10,000)[(c)]**	**Number**	**Rate(per 10,000)[(c)]**	**Rate difference[(d)]**
Nursing	782	21.4	37,298	21.1	0.4
Public health	309	8.5	5,945	3.4	5.1
Indigenous health	159	4.4	52	0.0	4.3
Other public health	150	4.1	5,893	3.3	0.8
Medical studies	175	4.8	14,456	8.2	–3.4
Rehabilitation therapies	82	2.2	12,893	7.3	–5.0
Dental studies	35	1.0	2,617	1.5	–0.5
Pharmacy	n.p.	n.p.	4,910	2.8	n.p.
Radiography	18	0.5	2,003	1.1	–0.6
Optical science	< 10	n.p.	642	0.4	n.p.
All undergraduate domestic students[(a)]	**1,415**	**38.8**	**79,433**	**44.8**	**–6.0**
Total enrolments[(e)]	**1,766**	**48.4**	**128,153**	**72.3**	**–23.9**

(a) The total undergraduate domestic students take into account the coding of Combined Courses to two fields of education. As a consequence, counting both fields of education for Combined Courses means that the total undergraduate domestic enrolment in this table is less than the sum of detailed fields of education.

(b) Medical studies, nursing, pharmacy, dental studies, optical science, public health, radiography, rehabilitation therapies.

(c) Using 2010 Australian population aged 15–64.

(d) Rate difference is Other students rate minus the Indigenous rate.

(e) Includes undergraduate, postgraduate, domestic and international students.

Higher education sector completions

- In 2010, there were 278 Indigenous graduate student completions in health related courses. Of these, 177 were completions of Indigenous undergraduate domestic students, which was a rate of 5 per 10,000 students. This was lower than the rate of undergraduate health-related course completions for other students in 2010 (9 per 10,000) (Table 3.20.4).
- The most common type of health-related course that Indigenous undergraduate students completed in 2010 was nursing (100) followed by public health (39) (Table 3.20.4).
- Approximately 1% of domestic students who completed a health-related course in 2010 identified as Aboriginal or Torres Strait Islander. Courses relating to public health had the highest proportion of Indigenous student completions (4%), followed by nursing (1%) (Table 3.20.4).
- Around one-third (34%) of all Indigenous students (including international students) who completed health-related courses in 2010 were aged 15–24 years. This compared with 30% of other students. Around 37% of Indigenous students who completed health-related courses were aged 25 years and above, compared with only 10% of other students (Table 3.20.5).

- In 2010, the rate of Indigenous students (domestic and international) competing higher education health-related courses were lower than that for other students for ages 15–24 and 25–34, but were similar for ages 35 and over (Figure 3.20.2).

Table 3.20.4: Undergraduate students(a) completions health-related courses(b), Indigenous and Other students, 2010

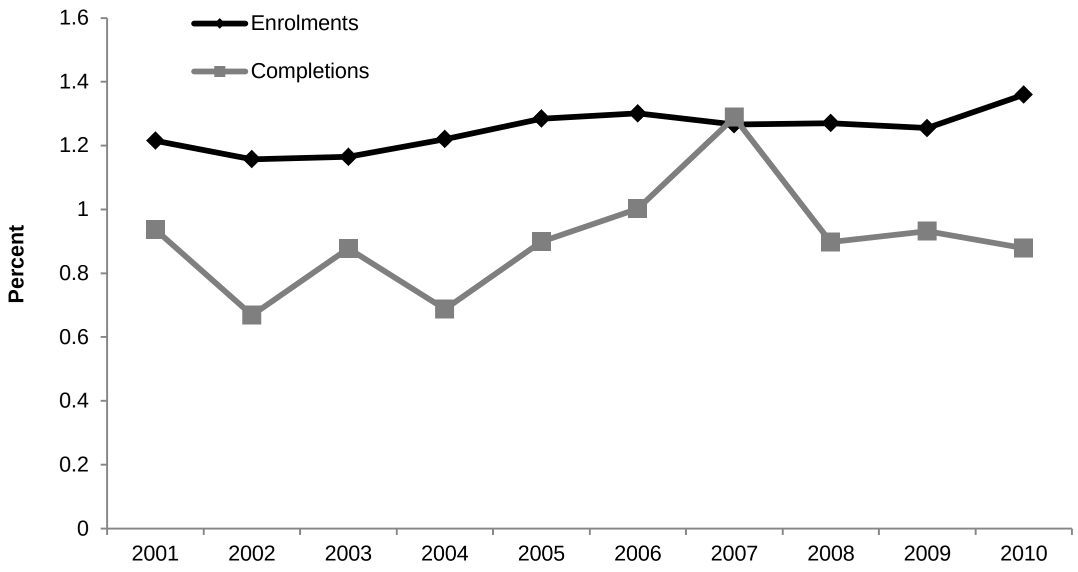
Time series

- During 2001 to 2010, there has been an upward trend in the number and rate of Indigenous students who have both enrolled in and completed undergraduate health-related courses (Table 3.20.6).
- However, over the same time period the proportion of Indigenous student enrolments have remained relatively stable and the proportion of Indigenous student completions have fluctuated somewhat (between 0.9% and 1.3%) (Table 3.20.7 and Figure 3.20.3).



Notes

1. Medical studies, nursing, pharmacy, dental studies, optical science, public health, radiography, rehabilitation therapies.
2. Includes domestic and international students.

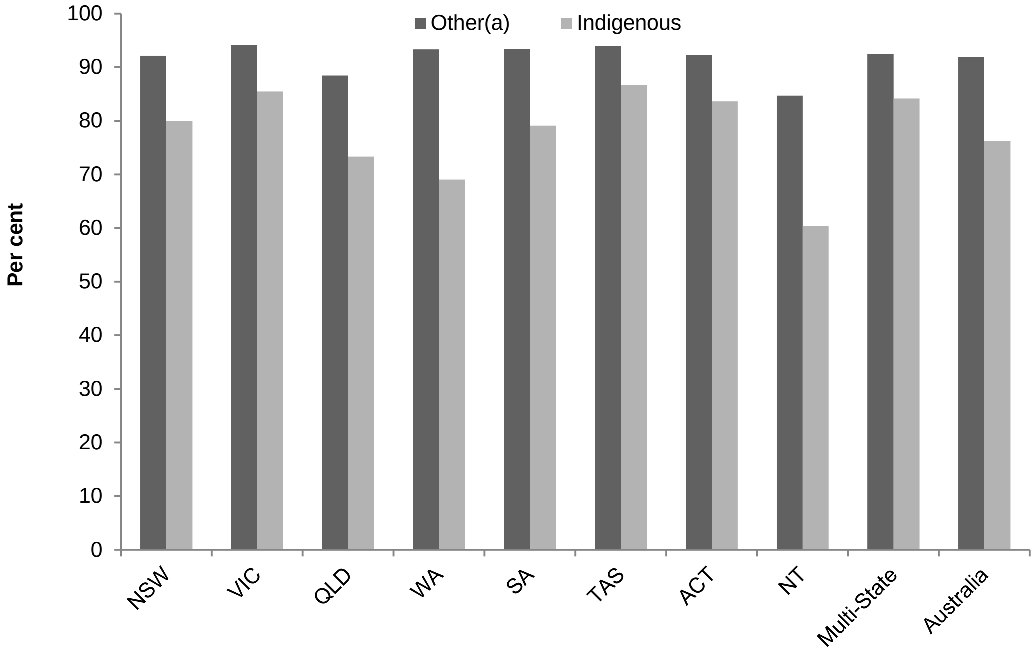
Progress rates

The progress rate for higher educational institutions is based on the proportion of units passed within a year compared with the total number of units enrolled.

- In 2010, the progress rate for Indigenous university students studying health-related courses was 76%. This compared with 92% for non-Indigenous university students studying health-related courses.
- The progress rate for Indigenous students varied by state and territory, ranging from 60% in the Northern Territory to 87% in Tasmania (Table 3.20.8 and Figure 3.20.4).



(a) Other includes those whose Indigenous status is unknown.

Vocational education and training (VET) sector enrolments

Data on Indigenous students enrolled in health-related courses in the VET sector are available from NCVER National VET Provider Collection. Data for 2010 are presented below.

- In 2010, there were 5,100 Indigenous enrolments in health-related courses in the VET sector; this represented about 5% of all students enrolled in VET courses (Tables 3.20.9 and 3.20.14).
- The most common type of health-related courses in which Indigenous VET students were enrolled in for 2010 was public health (2,796 enrolments) followed by nursing (464 enrolments) (Table 3.20.9).
- In 2010, the enrolment rate for Indigenous students in health related courses was higher than that of non-Indigenous students (147 per 10,000 compared with 70 per 10,000).
- In 2010, the proportion of Indigenous students enrolled in VET sector health-related courses ranged from 0.9% in the Australian Capital Territory to 51% in the Northern Territory (Table 3.20.10).
- The proportion of Indigenous students enrolled in VET sector health-related courses increased between 2003 and 2010 (from around 4% to 5%) (Tables 3.20.11 and 3.20.12).

Vocational education and training sector completions

- In 2010 there were 554 Indigenous completions in health-related courses in the VET sector; this represented 4% of students, aged 15–64, who completed VET courses (Table 3.20.14). Completions were at a much higher rate for Indigenous students (16 per 10,000) than for non-Indigenous students (10 per 10,000) (Table 3.20.13).
- The most common type of health-related course completed by Indigenous VET students in 2010 was public health (379 completions) followed by nursing (54 completions). Indigenous students as a proportion of the total students completing these courses were 8% and 1% respectively (Table 3.20.14).
- Over the period 2003–2010 the rate of VET health-related course completions doubled for both Indigenous and other students (Tables 3.20.15 and 3.20.16).
- The proportion of Indigenous completions dropped from 7.0% to 3.4% between 2002 and 2003. From 2004 to 2010 the proportion varied between 2.6% and 4.8% (Table 3.20.17 and Figure 3.20.5).

Load pass rates

The VET load pass rate indicates the extent to which students pass assessment in an assessable module or unit of competency. Load pass rates are calculated as the number of nominal hours supervised in assessable modules or units of competency completed with a pass assessment divided by the total nominal hours supervised in assessable modules or units of competency.

- In 2010, the VET load pass rate for Indigenous students studying health-related courses was 79%, compared with 86% for other students. The load pass rate for Indigenous students studying health-related courses ranged from 71% in Western Australia to 88% in South Australia (Table 3.20.18 and Figure 3.20.6).

Aboriginal and Torres Strait Islander health worker occupations

Tables 3.20.19 and 3.20.20 present the number and rate of VET sector students completing a course aimed at Indigenous health workers in 2010.

- In 2010, 283 VET sector students had completed a course aimed at Indigenous health worker occupations in Australia. The majority of these course completions were at the certificate III and IV level (229, or 81%) (Table 3.20.19).
- New South Wales had the highest number of students completing a course aimed at Indigenous health worker occupations (96), followed by Queensland (78).
- Of all VET sector students who had completed a course aimed at Indigenous health worker occupations in 2010, (199) 70% were female and (84) 30% were males (Table 3.20.20).

Data quality issues

DEEWR Higher Education Schools Statistics Collection

The Higher Education Schools Statistics Collection comprises information on enrolments and award completions from public and private higher education institutions that are required to report to DEEWR.

Institutions receive detailed written documentation about what information is required to be furnished in the form of an electronic help file. Universities design and produce their own statistical information (enrolment) forms. These are designed to be used by institutions to collect the required information from students. DEEWR has provided institutions with suggested wording for questions relating to Indigenous status, language spoken at home and disability (ABS 2009).

Approximately 3% of students in this data collection have a 'not stated' Indigenous status. At the moment these are recorded as non-Indigenous, although plans are under way to record the 'not stated' responses separately.

National Centre for Vocational Education Research data

This collection gathers information from providers (in receipt of public VET funding) about activity of the VET system in Australia. The collection encompasses all delivery funded wholly or in part from public funds.

NCVER maintains a database of information on persons undertaking vocational education and training. Each state and territory collates data from their training providers on a student, course and module/unit of competency basis. These data are compiled into AVETMISS format and validated by each training organisation before being submitted to NCVER. The data are then further validated and quality checked for inconsistencies before being used for the production of statistical reports (ABS 2009).

Non-identification rates for Indigenous students in these data are high. Care also needs to be taken when comparing data across jurisdictions for load pass rates, as average module durations vary across jurisdictions (SCRGSP 2005).

List of Figures

3.21 Expenditure on Aboriginal and Torres Strait Islander health compared to need

Expenditure on health for Aboriginal and Torres Strait Islander people. This measure is presented on both a total population basis and per capita basis and disaggregated to reflect expenditure on acute health care, primary health care and population health.

Data sources

Data for this measure come from the latest available health expenditure report—*Expenditure on health for Aboriginal and Torres Strait Islander people 2008–09* published by the Australian Institute of Health and Welfare (AIHW 2011).

Health Expenditure Data

The AIHW reports biennially on expenditure on health for Aboriginal and Torres Strait Islander people. The latest report in the series, *Expenditure on health for Aboriginal and Torres Strait Islander people 2008–09,* was released in 2011.

There are a number of difficulties in reporting on Indigenous health expenditure, including limitations in the scope and definition of health expenditure, as well as inconsistencies in reporting expenditure on health goods and services across data providers. Under-identification (where Indigenous people are not identified as such) and under-coverage (where the sample does not reflect the true population structure) of Indigenous Australians in health data collections (such as hospital separations) are further issues that affect data quality. Although under-identification adjustments are made to the data, the adjusted estimates may be an overestimate or under-estimates of actual health service use and expenditure by Indigenous people. The allocation of expenditure to Indigenous people either on an overall population or per capita basis should also be treated with caution, as Indigenous population estimates have similar issues of under-coverage and under-identification (AIHW 2009).

Estimates of the level of Indigenous under-identification were used to adjust some reported expenditure. In some states and territories, a single state wide average under-identification adjustment factor was applied. In others, differential under-identification factors were used, depending on the region in which the particular service(s) were located. In some jurisdictions, no Indigenous under-identification adjustment was considered necessary.

Analyses

Total government expenditure

Expenditure on health goods and services

Total government expenditure on health goods and services for Indigenous Australians is presented in Tables 3.21.1.

- Expenditure on health goods and services for Aboriginal and Torres Strait Islander people during 2008–09 was estimated at $3.7 billion (Table 3.21.1) or approximately 3.5% of total health expenditure. Almost three-quarters of this expenditure (73%) were related to two major program areas—goods or services provided in hospitals ($1,868 million) and community health services ($823 million).
- On a per person basis, average expenditure on health goods and services for Indigenous people was $6,787, which was 39% higher than the expenditure for non-Indigenous Australians ($4,876) (Table 3.21.1).
- In four major program areas, average per person expenditure on services for Indigenous people was greater than for non-Indigenous Australians (Table 3.21.1). These were community health services, which had an Indigenous to non-Indigenous expenditure ratio per person of 6.9; patient transport with a ratio of 2.8; public health (which includes other recurrent expenditure on health, not elsewhere classified, such as family planning previously reported under 'Other health services (nec)') with a ratio of 2.5; and public hospitals with a ratio of 2.3. In contrast, average expenditure on goods and services provided outside public hospitals was often lower for Indigenous people than for non-Indigenous people. For example, average expenditure on medical services and medications were both around half that for non-Indigenous Australians.

(continued)

Table 3.21.1 (continued): Expenditure on health (current prices) for Indigenous and non-Indigenous people, by type of health good or service, 2008–09

(a) Excludes dental services, patient transport services, community health services, public health and health research undertaken by the hospital.

(b) Admitted patient expenditure estimates adjust for Aboriginal and Torres Strait Islander under-identification, except for Tasmania.

(c) Includes state/territory government expenditure for services provided for public patients in private hospitals.

(d) Includes other recurrent expenditure on health, not elsewhere classified, such as family planning previously reported under ‘Other health services (n.e.c.)’.

(e) Expenditure estimates include depreciation (capital consumption).

Source: AIHW 2011.

Expenditure on primary and secondary/tertiary services

Primary health services are those provided to whole populations (community health services and public health activities or health promotion) and those provided in, or flowing from, a patient-initiated contact with a health service. Secondary/tertiary services are those generated within the system by referral, hospital admission, and so on. Because distinctions are not always easy to make, there is some approximation in these estimates.

- In 2008–09, the total expenditure on primary health services for Indigenous people was $1,681 million while for secondary and tertiary health services, the total expenditure was $1,904 million (Table 3.21.2).
- In 2008–09, average expenditures per person on both primary and secondary/tertiary care services were higher for Indigenous Australians than for non-Indigenous people, although the ratio was marginally higher for secondary/tertiary care—1.7:1 compared with 1.4:1 (Table 3.21.3). Higher spending on primary care services for Indigenous Australians came largely from a much higher use of the community health services sector, including those provided through the Aboriginal Community Controlled Health Services (ACCHS).
- The higher level of spending on secondary/tertiary services for Indigenous people was largely in hospitals. Expenditure on secondary/tertiary hospital services for Indigenous people was $3,135 per person compared with $1,429 per person for non-Indigenous people. Expenditure on primary medical services and medications was lower for Indigenous people ($328 and $294 per person, respectively) than for non-Indigenous people ($517 and $644 per person, respectively) (Table 3.21.3).

Funding of health services

Funding for health goods and services for Indigenous people is presented in Table 3.21.4.

- Governments provided an estimated 91.0% of the funding used to pay for health goods and services for Aboriginal and Torres Strait Islander people during 2008–09; non-government sources such as out-of-pocket payments by users of services provided the remainder of the funding (Table 3.21.4).
- The Australian Government's funding was similar for Indigenous and non-Indigenous Australians (43% and 45%, respectively), although the shares of funding provided by both the state and territory governments and the non-government sector were different for Indigenous and non-Indigenous Australians. The states and territories provided nearly half (48%) of the funding for Aboriginal and Torres Strait Islander people, compared with 24% for non-Indigenous Australians. Non-government sources, on the other hand, provided a much lower share of the funding for services for Indigenous people (9.0%) than for non-Indigenous people (30.5%). Non-government payments include injury compensation insurers, private health insurers and out-of-pocket payments by users of services.

The main reason for the differences between Indigenous and non-Indigenous funding shares of the states and territories and non-government sources was the greater reliance by Indigenous people on publicly provided services, particularly public hospitals that are funded by the states and territories. Indigenous Australians also have a lower use of privately provided services than non-Indigenous Australians.

- The top three areas of funding for Indigenous Australians in 2008–09 were public hospital services ($1,828 million), community health services ($823 million) and medical services ($266 million).
- For non-Indigenous people, the top three areas of funding were public hospital services ($31,594 million), medical services ($19,553 million) and medications ($15,034 million). Of the hospital funding, almost one-quarter (20.8%) was by private hospitals, compared with only 2.1% in the case of Indigenous people.

Source: AIHW 2011.

Australian Government expenditure

On a per person basis, expenditure on health goods and services by the Australian Government amounted to $1,673 per Indigenous person in 2008–09, compared with $1,418 for non-Indigenous people. In 2008–09, the total expenditure funded through ACCHSs for Indigenous Australians was $314.6 million. Most of this expenditure was administered by the Office of Aboriginal and Torres Strait Islander Health (OATSIH). Per person expenditure through ACCHSs services was $577 for Indigenous Australians compared with $2.2 for non-Indigenous Australians (AIHW 2011).

State/territory government expenditure

State/territory government expenditure on health goods and services for Indigenous Australians is presented in Table 3.21.5.

- In 2008–09, state and territory governments were estimated to have spent, on average, $4,758 per Indigenous Australian compared with $1,915 per non-Indigenous Australian. This represents an Indigenous/non-Indigenous expenditure ratio of 2.5:1.
- In all the major types of health goods and services, states and territories overall spent more per person for Indigenous people than for non-Indigenous people (Table 3.21.5). Expenditure on community health for Indigenous people was almost five times that for non-Indigenous people, expenditure on public health was almost three times that for non-Indigenous people and expenditure on admitted patient services in acute-care hospitals was more than twice that for non-Indigenous people.
- The Northern Territory ($7,525.8) and South Australia ($6, 743.0) had the highest average expenditure per person for Indigenous people. Tasmania, which had the lowest average expenditure per person for Indigenous people ($1,434), was the only jurisdiction where the estimated expenditure per person for Indigenous Australians was lower than that for non-Indigenous people ($1,898), but these numbers should be treated with caution (Table 3.21.5).

(a) Australian Capital Territory per person expenditure estimates are not calculated because estimates for the Australian Capital Territory include substantial expenditures for New South Wales residents. As a result, the Australian Capital Territory population is not an appropriate denominator.

(b) Admitted patient expenditure adjusted for Aboriginal and Torres Strait Islander under-identification, except for Tasmania.

(c) Includes other recurrent expenditure on health, not elsewhere classified, such as family planning previously reported under ‘Other health services (n.e.c.)’.

(d) Health administration costs for New South Wales, Victoria, Tasmania and the Northern Territory are zero, as these jurisdictions have allocated administrative expenses into the functional expenditure categories in the table.

Source: AIHW 2011.

Regional health expenditure

Estimated average health expenditures per person by remoteness area for Indigenous and non-Indigenous people are presented in Table 3.21.6.

- In 2008–09, average expenditures on health for Indigenous Australians were lowest in *Inner regional* areas and *Major cities*.
- Expenditure per capita on hospital care within public hospitals for Indigenous people was greatest in the more remote areas; however, in private hospitals, expenditure per capita was the least in *Remote* and *Very remote* areas for Indigenous Australians.
- Pharmaceutical Benefits Scheme (PBS) expenditures, were greater in more remote areas where the section 100 arrangements apply. Under section 100 of the *National Health Act 1953*, clients of approved remote area Aboriginal Health Services (AHSs) are able to receive PBS medicines directly from the AHS at the time of medical consultation, without the need for a normal prescription form, and without charge.

(b) Excludes the following: allied health services, optometry and dental services.

(c) Excludes RPBS, and highly specialised drugs dispensed from public and private hospitals.

(d) Difference is equal to Indigenous minus non-Indigenous.

Source: AIHW 2011. Expenditure on health for Aboriginal and Torres Strait Islander people 2008–09 - An analysis by remoteness and disease; Supplementary table 1.

Changes in health expenditure and funding over time

This section describes the changes over time in selected components of health expenditure for Aboriginal and Torres Strait Islander people. To enable reliable comparison, expenditure for all years is presented in constant 2008–09 prices. Constant price expenditure adjusts for the effects of inflation by using either the annually re-weighted chain price indexes produced by the ABS or implicit price deflators derived by the ABS or AIHW.

The definition of health expenditure changed in 2007 to exclude high-care residential aged care, which was instead classified as welfare expenditure.

For the purpose of comparison, high-care residential aged care expenditure has been omitted from all of the years' estimates in the tables and figures below. This allows for the comparison of health expenditure estimates over time, as well as providing estimates that relate more directly to those in *Health expenditure Australia 2008–09* (AIHW 2010b).

Total government health expenditure

- Government expenditure per person on health for Indigenous Australians has increased substantially over the 7 years, reaching $6,431 per person in 2008–09. Over this period, Indigenous health expenditure grew at an average annual rate of 5.6% (Table 3.21.7)**.**
- Between 2001–02 and 2008–09, government health expenditure per person for Aboriginal and Torres Strait Islander people rose by 46.8%. Of the total increase, state and territory governments' expenditure on admitted patient services contributed 51%.This increase amounted to $1,049 more per person in 2008–09 than in 2001–02. State and territory governments' expenditure per person grew by 41.4%between 2001–02 and 2008–09, and the Australian Government's expenditure by 64.8 %(Table 3.21.7).
- Between 2006–07 and 2008–09, per person government health expenditure on Aboriginal and Torres Strait Islander people increased by $910 (in constant dollars). This represented an annual growth rate of 7.9%, which is higher than the corresponding annual growth rate for the 5 years before 2006–07 (4.7%). Expenditure per person was higher in all health categories for 2008–09 compared with 2006–07 (Table 3.21.7).

Australian government expenditure

- MBS and PBS benefits contributed a substantial component of the Australian Government growth in health expenditure per person for Aboriginal and Torres Strait Islander people, accounting for 60.2% of Australian government growth between 2001–02 and 2008–09 (Table 3.21.7). Some of the increase in Indigenous health expenditure per person may have been due to improvements in data collection rather than actual change (AIHW 2011).
- Australian Government expenditure growth accounted for 26.3% of the growth in government Indigenous expenditure between 2006–07 and 2008–09. MBS and PBS expenditure accounted for 12.8% of the total growth, and grants to ACCHSs to 6.9%. The growth in PBS expenditure for Aboriginal and Torres Strait Islander people was particularly marked, increasing by 42.0% over the 2 years from 2006–07 to 2008–09 (Table 3.21.7).
- Australian Government expenditure on Indigenous-specific health services has continuously increased since 1995–96. In 2010–11, the total Commonwealth funding for Indigenous-specific programs was $576 million: a real growth of 265% since 1996–96 (Table 3.21.8).

Table 3.21.7: Government health expenditure per person for Aboriginal and Torres Strait Islander people, constant prices(a), 2001–02 to 2008–09(b)(c)(d)

Other	362.2	576.2	470.8	565.1	56.0	6.6	20.0	9.6
Total governments	**4,380.3**	**4,624.9**	**5,521.6**	**6,431.2**	**46.8**	**5.6**	**16.5**	**7.9**

(a) Constant price health expenditure for 2001–02 to 2008–09 is expressed in terms of 2008–09 prices. Refer to the Appendix for further details.

(b) Indigenous population estimates used to estimate the expenditure figures are all derived from 2006-census base.

(c) Estimates for 2001–02 and 2004–05 exclude depreciation but those for 2006–07 and 2008–09 include depreciation. This reduces the 2004–05 state/territory government numbers by about 5%, but has minimal impact on the Australian Government numbers.

(d) In 2007, expenditure on high-care residential aged care services was reclassified from health services to welfare services. To enable comparisons with previous estimates, high-care residential aged care expenditure has been subtracted from the 2001–02 and 2004–05 estimates in this table.

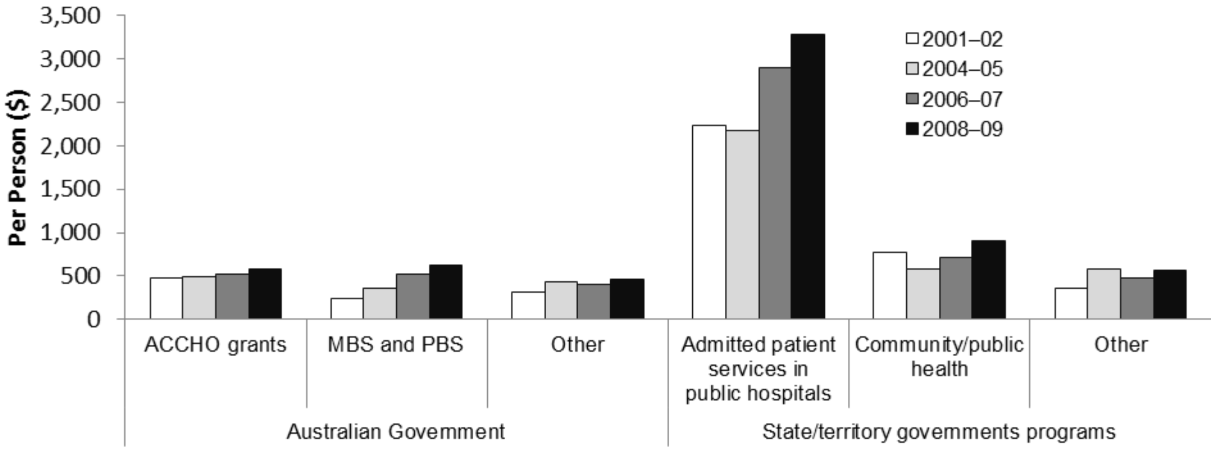
State/territory government expenditure

Health expenditure per Aboriginal and Torres Strait Islander person incurred by state and territory government programs and Australian Government programs over the period 2001–02 and 2008–09 are presented in Figure 3.21.1.

- Between 2006–2007 and 2008–09, per person health expenditure for Indigenous persons on state and territory government health programs (including public hospitals, community and public health and other expenditure) and Australian Government health programs (including ACCHS, MBS and PBS, and other expenditure) all increased (Figure 3.21.1).
- Over this period, the largest increase in this expenditure was incurred by state and territory governments on admitted patient services in public hospitals. Expenditure increased from $2,899 per person in 2006–07 to $3,283 in 2008–09. Community and public health expenditure increased from $717 to $909 and other expenditure increased from $909 to $923 over the same period (Figure 3.21.1).



Note: In 2007, expenditure on high-care residential aged care services was reclassified from health services to welfare services. To enable comparisons with previous estimates, high-care residential aged care expenditure has been subtracted from the 2001–02 and 2004–05 estimates in this table.

Figure 3.21.1: Health expenditure per Aboriginal and Torres Strait Islander person, in constant prices, by area of expenditure — 2001–02 to 2008–09

Medicare Benefits Schedule (MBS) and the Pharmaceutical Benefits Scheme (PBS)

This section presents estimates of health expenditure on Aboriginal and Torres Strait Islander people through the MBS and PBS.

In 2008–09, an estimated $206 million of Australian Government expenditure on health goods and services for Aboriginal and Torres Strait Islander people was through the MBS, and an estimated $136 million through the PBS (AIHW 2011).

- MBS expenditure per person was higher for non-Indigenous Australians than for Indigenous Australians across all remoteness areas. The largest gap in expenditure between Indigenous and non-Indigenous was observed in inner and outer regional areas and the smallest gap was in remote areas (Table 3.21.9).
- PBS expenditure per person was lower in all remote areas with biggest expenditure gap occurring in outer regional areas and smallest gap was in remote areas (Table 3.21.9).
- The expenditure per hospital separations was higher for Indigenous Australians than non-Indigenous Australians. The greatest difference was observed for non-communicable diseases such as genitourinary diseases and injuries. For non-Indigenous Australians, higher expenditure per person was due to the treatment of neoplasms, musculoskeletal and connective tissue disorders (Table 3.21.10).
- For expenditure on potentially preventable hospital separations, treatment for chronic conditions such as diabetes complications and chronic obstructive pulmonary disease attributed to the greatest difference between Indigenous and non-Indigenous Australians (Table 3.21.11).

(a) Includes hospital separations data for all states/territories. Hospital separation rates differ from those published in Australian hospital statistics: 2008–09 (AIHW 2010a) because the estimates in this report relate to principal diagnoses only, have been adjusted for Indigenous under-identification and are crude rates (rather than age-standardised rates).

(b) Difference is equal to Indigenous minus non-Indigenous.

Source: AIHW 2011. Expenditure on health for Aboriginal and Torres Strait Islander people 2008–09 - An analysis by remoteness and disease; Supplementary table 8.

Data quality issues

Health Expenditure Data

The AIHW draws upon both expenditure data and service use data to prepare Indigenous health expenditure estimates.

The quality of Indigenous service use data is of varying quality, as there is widespread non-reporting of Indigenous status or under-identification in administration records. Although the quality of Indigenous service use data such as admitted patient data is improving, under-identification of Aboriginal and Torres Strait Islander people in these data sets remains a major issue.

The source of data used to estimate health expenditure for Indigenous and non-Indigenous Australians through Aboriginal Community Controlled Health Organisations (ACCHOs) has changed slightly for 2008–09 estimates. Past estimates for 2004–05 and 2006–07 used information from the Service Activity Report database, which was a joint project of the Office for Aboriginal and Torres Strait Islander Health (OATSIH) and the National Aboriginal Community Controlled Health Organisation. The database collected service level data on health care through an annual questionnaire completed by every Australian Government-funded Aboriginal and Torres Strait Islander primary health care service. In 2008–09, however, it was replaced with the new OATSIH Service Report database, which also includes data previously collected under the Drug and Alcohol Service Report, and Bringing Them Home and Link Up Counsellors data collections.

Under-identification

Estimates of the level of Indigenous under-identification were used to adjust admitted patient expenditure estimates for New South Wales, Victoria, Queensland, South Australia, Western Australia and the Northern Territory (public hospitals only). In some states and territories, a single state-wide average under-identification adjustment factor was applied. In others, differential under-identification factors were used, depending on the region in which particular service(s) were located (AIHW 2011).

As the AIHW studies on Indigenous identification in hospitalisation data did not include private hospitals, an adjustment factor of 54% for private hospitals was derived from the analysis of linked hospital morbidity data from New South Wales.

Expenditure estimates

Some of the expenditure patterns in this report may be influenced by variations in the completeness of Indigenous identification, despite the adjustments made for under-identification. The use of scaled up MBS and PBS data based on the level of VII enrolment is one such example. It is possible that health expenditure estimates for Aboriginal and Torres Strait Islander people may slightly overestimate or underestimate the actual level of health expenditure. As a result, estimating health expenditure for Indigenous Australians is an evolving field, and conclusions should be drawn with caution.

In addition, while every effort has been made to ensure consistent reporting and categorisation of expenditure on health goods and services, in some cases there are inconsistencies across expenditure data providers. These result from limitations of financial reporting systems and/or different reporting mechanisms.

Time series estimate comparisons

The definition of health expenditure changed in 2007 to exclude high-care residential aged care, which was instead classified as welfare expenditure.

For the purpose of comparison, high-care residential aged care expenditure has been omitted from all of the years' estimates to allow for the comparison of health expenditure estimates over time.

There was a change in the method for estimating MBS and PBS expenditure for the 2006–07 and 2008–09 reports in this series. The revised method involves the use of Medicare VII data to estimate expenditure on medical services, such as general practitioner, specialist services, pathologist services, imaging services, and prescription pharmaceuticals provided to Aboriginal and Torres Strait Islander people. Prior to this, data from the Bettering the Evaluation and Care of Health (BEACH) survey data were used in these estimates. This change may have contributed to the increase in MBS and PBS expenditure estimates in 2006–07 and 2008–09 reports compared with those in the 2001–02 and 2004–05 reports (AIHW 2011).

3.22 Recruitment and retention of staff

The recruitment and retention of qualified clinical and management staff to provide effective health care to meet Aboriginal and Torres Strait Islander health-care needs

Data sources

National data for broad measures of recruitment and retention are not available from existing national administrative health or workforce databases. There are, however, a small number of limited collections that are relevant to this measure. Data for this measure come from the National Health Workforce Data Set, general practitioner (GP) data held by the Australian Government Department of Health and Ageing (DoHA), OATSIH Services Reporting (OSR) Data Collection and the Rural Workforce Agency National Minimum Data Set.

National Health Workforce Data Set

The AIHW, in collaboration with Health Workforce Australia, is the custodian of the National Health Workforce Data Set (NHWDS) that describes these professionals and the work they do.

The NHWDS combines data from the National Registration and Accreditation Scheme (NRAS) with health workforce survey data collected when annual registrations are renewed. The mandatory registration process is administered by the Australian Health Practitioner Regulation Agency (AHPRA) and includes an optional survey that collects additional demographic and workforce information.

All practitioners in these professions must be registered with the AHPRA to practise in Australia, and this applies whether they trained in Australia or overseas. The AHPRA manages the NRAS, which replaced jurisdiction-based registration with a single national registration and accreditation system. As part of this scheme, the AHPRA supports National Health Practitioner Boards, which regulate registered health professions under nationally consistent legislation. Registration for each profession is granted by the relevant boards, subject to applicants meeting the standards and policies set by each.

At its introduction, the NRAS covered registration for 10 health professions, with another four scheduled for inclusion from 1 July 2012. Since 1 July 2010, these professions have been regulated: chiropractors, dental practitioners (including dentists, dental hygienists, dental prosthetists and dental therapists), medical practitioners, nurses and midwives, optometrists, osteopaths, pharmacists, physiotherapists, podiatrists, and psychologists. From 1 July 2012, these health professions are included: Aboriginal and Torres Strait Islander health practitioners, Chinese medicine practitioners, medical radiation practitioners, and occupational therapists. In all, this represents more than 530,000 registered health professionals.

DoHA general practice statistics

The Commonwealth Department of Health and Ageing holds data on the number of GPs in Australia by remoteness area and Statistical Local Area (SLA). On 1 July 2009 the Rural, Remote and Metropolitan Areas (RRMA) system was replaced by the Australian Standard Geographical Classification – Remoteness Areas (ASGC-RA) system.

Rural Workforce Agency National Minimum Data Set

The Rural Workforce Agency National Minimum Data Set is a national data set based on annual surveys conducted by each state and territory Rural Workforce Agency. The data set is compiled through the Australian Rural and Remote Workforce Agencies Group. These data are available by remoteness area and duration of practice. They do not directly answer the broader retention and recruitment questions, but will provide useful information for this measure.

OATSIH Services Reporting Data Collection

The Australian Institute of Health and Welfare (AIHW) has collected data from Aboriginal and Torres Strait Islander primary health care services, stand-alone substance use services, and Bringing Them Home and Link Up counselling services that received funding through the Office for Aboriginal and Torres Strait Islander Health (OATSIH) for 2008–09 onwards.

OATSIH-funded services include both Indigenous community controlled health organisations and non-community controlled health organisations. Note that the OATSIH Services Reporting (OSR) only includes Aboriginal and Torres Strait Islander health organisations that receive at least some Australian Government funding to facilitate access to primary health care.

This collection, referred to as the OSR data collection replaces the Service Activity Reporting (SAR), Drug and Alcohol Services Reporting (DASR), and Bringing Them Home and Link Up counselling data collections previously collected by the OATSIH.

The counting rules used in OSR data analyses treats each auspice service as a single service and this yields a larger numerator and denominator when calculating rates whereas in earlier collections (SAR and DSAR) only the higher level service was counted. For example, a higher level service could have five auspice services under it and in OSR these will be counted as five individual services whereas in SAR and DSAR it was counted as a single service. While this change only marginally affects the aggregate rates, caution should be exercised when comparing rates with earlier data collection periods.

The OSR data collection included 300 Australian Government-funded Aboriginal and Torres Strait Islander primary health-care services in 2010–11.

Analyses

Supply of health professionals

Data on the supply of health professionals are available from the National Health Workforce Data Set (NHWDS): medical practitioners 2010, AIHW Nursing and Midwifery Labour Force Survey 2009, 2002 Physiotherapy Labour Force Survey, 2003 Podiatry Labour Force Survey, 2003 Psychology Labour Force Survey and 2002–03 Occupational Therapy Labour Force Survey. Information from these data sources are summarised below. Information is also presented on the dental labour force from the AIHW Dental Statistics and Research unit.

Medical practitioners

- In 2010, there were 58,192 registered medical practitioners in Australia of whom 52,497 (90%) were employed in medicine in Australia (excluding Queensland and Western Australia for which data were not available) (Table 3.22.1).
- The proportion of registered medical practitioners who were employed in medicine ranged from 92% in the Australian Capital Territory to 95% in the Northern Territory (Table 3.22.1).
- Half (50%) of all registered medical practitioners in the six states combined (New South Wales, Victoria, South Australia, Tasmania, the Australian Capital Territory and the Northern Territory) who were employed in medicine overseas, were registered in New South Wales. Similarly, nearly half (49%) of all registered medical practitioners who were not employed were New South Wales registrants.
- Between 2006 and 2010, the number of medical practitioners employed in medicine increased by 13% from 46,336 to 52,497. Differences between the questionnaires previously administered by jurisdictions, as well as changes to the new nationally standardised survey tool have resulted in a slight change in the pattern of responses to the employment-related questions. As such, comparing data over time should be done with caution (AIHW 2012b).

Table 3.22.1: Labour force status of registered medical practitioners, by state/territory, 2010

Labour force status	NSW	Vic	Qld[(a)]	WA[(a)]	SA	Tas	ACT	NT	Australia[(b)]
Employed in medicine	23,549	18,883	. .	. .	5,984	1,717	1,523	818	52,479
On extended leave	596	586	. .	. .	152	48	48	24	1,526
Not employed in medicine	146	98	. .	. .	10	n.p.	10	n.p.	299
Employed in medicine overseas	304	210	. .	. .	38	24	24	7	2,128
Not employed in Australia	248	174	. .	. .	45	23	6	11	566
Retired from regular work in medicine	554	358	. .	. .	148	n.p.	41	n.p.	1,176
Total registered	**25,398**	**20,309**	**. .**	**. .**	**6,376**	**1,854**	**1,653**	**864**	**58,192**
Per cent registered practitioners employed in medicine	**92.7**	**93.0**	**. .**	**. .**	**93.8**	**92.6**	**92.2**	**94.7**	**90.2**

(a) Data exclude Queensland and Western Australia due to their registration period closing after the national registration deadline of 30 September 2010.

(b) Data include employed medical practitioners who did not state or adequately describe their state or territory of principal practice and employed medical practitioners who reside overseas. Therefore, state and territory totals may not sum to the national total. The sum of state and territory numbers of registered medical practitioners (excluding Queensland and Western Australia) is 56,454 compared with the national figure of 58,192; a difference of 1,738 medical practitioners (1.3% of all registered medical practitioners, excluding Queensland and Western Australia).

Source: National Health Workforce Data Set: medical practitioners 2010.

Registered and enrolled nurses

- The total number of nurses identified in 2009 by the Nursing and Midwifery Labour Force Census was 320,982, comprising 260,121 registered nurses and 60,861 enrolled nurses. The number of registered and enrolled nurses in the labour force (that is, employed in or looking for work in nursing in Australia) increased by 9.3% between 2007 and 2009, from 277,297 to 291,246 (AIHW 2012a; Table 3.22.2).

- The proportion of registered nurses employed in nursing in Australia in 2009 was 87% (255,040), and ranged from 80% in New South Wales to 93% in Tasmania. Of the registered nurses who were not employed in nursing, the majority were not looking for work in nursing (20,708) or were on extended leave (8,440) (Table 3.22.2).
- The proportion of enrolled nurses employed in nursing in Australia in 2009 was 85% (51,711), ranging from 77% in the Northern Territory to 91% in South Australia. Of the enrolled nurses not employed in nursing, 1,791 were looking for work in nursing while 5,795 were not (Table 3.22.2).

Table 3.22.2: Labour force status of registered and enrolled nurses, by state/territory(a), 2009

(a) State and territory estimates for 2009 should be treated with caution due to low response rates in some jurisdictions.

Source: Nursing and midwifery labour force (AIHW 2011).

Physiotherapists

- In 2002, there were 15,967 physiotherapists registered with state/territory physiotherapist registration boards throughout Australia (excluding the Northern Territory). This represents an 11% increase in the number of physiotherapists between 1998 and 2002 (AIHW 2011).
- The AIHW 2002 Physiotherapy Labour Force Survey showed that there were 13,446 registered physiotherapists throughout New South Wales, Victoria, Queensland, South Australia, and the Australian Capital Territory, of whom 10,728 (80%) were working in physiotherapy. The proportion of registered physiotherapists who were working in physiotherapy in 2002 ranged from 74% in New South Wales to 87% in Victoria (Table 3.22.3).
- From the 2002 AIHW survey, the FTE rates could only be calculated for three jurisdictions (Victoria, 70 per 100,000; South Australia, 72; and the Australian Capital Territory, 81) (AIHW 2011).
- Of the registered physiotherapists who were not working in physiotherapy in 2002, the majority were not actively looking for work in physiotherapy (1,382).

Table 3.22.3: Registered physiotherapists: labour force status and field of physiotherapy by state/territory, NSW, Vic, Qld, SA and ACT, 2002

Labour force status/field	NSW	Vic[(a)]	Qld	SA	ACT	Total[(b)]
Physiotherapy labour force	4,370	3,405	1,935	1,204	286	11,201
Total working in physiotherapy	*4,191*	*3,257*	*1,849*	*1,156*	*274*	*10,728*
Clinical physiotherapist	3,955	2,931	1,717	1,051	258	9,913
Non-clinical physiotherapist	236	326	133	104	16	815

Overseas	499	144	148	64	8	863
Not looking for work in physiotherapy	814	178	278	85	26	1,382
Total registered physiotherapists	**5,683**	**3,728**	**2,362**	**1,353**	**320**	**13,446**
Percentage of physiotherapists employed in physiotherapy	73.7	87.4	78.3	85.4	85.6	79.8

(a) The numbers for Victoria should be treated with caution. The increase from 1998 to 2002 in the number employed (21.7%), and the associated declines in the numbers 'looking for work in physiotherapy' and 'not in the labour force', are higher than would be expected from the increase in registrations over the same period (7.7%).

(b) Excludes Western Australia, Tasmania and the Northern Territory, which were not surveyed in 2002.

Source: Physiotherapy Labour Force Survey, 2002 (AIHW 2006a).

Podiatrists

- In 2003, there were 2,361 podiatrists registered with state/territory boards throughout Australia (excluding the Northern Territory). This represents a 15% increase in the number of podiatrists between 1999 and 2003 (AIHW 2011).
- The 2003 AIHW Podiatry Labour Force Survey showed there were 1,988 registered podiatrists in New South Wales, Victoria, Queensland, South Australia and Tasmania in 2003, of whom 1,820 (92%) were working in podiatry. The proportion of podiatrists working in podiatry ranged from 89% in Victoria to 97% in South Australia (Table 3.22.4).
- The supply of podiatrists varied between states, ranging from 7.7 per 100,000 population in Queensland to 19.7 per 100,000 population in South Australia (AIHW 2010).
- Of the registered podiatrists who were not working in podiatry in 2002, the majority were not actively looking for work in podiatry (112).

Table 3.22.4: Labour force status of registered podiatrists by state/territory, NSW, Vic, Qld, SA and Tas, 2003

Labour force status	NSW	Vic	Qld	SA	Tas	Total

Psychologists

- In 2004–05 there were 22,175 psychologists registered with Psychologist Registration Boards in Australia (excluding the Australian Capital Territory and the Northern Territory). This represents an increase in the number of psychologists between 1999–00 and 2004–05 in all jurisdictions. The increase ranged from 20% in Western Australia to 59% in New South Wales (AIHW 2011).
- The 2003 AIHW Psychology Labour Force Survey showed there were 16,094 registered psychologists in New South Wales, Victoria, Queensland, South Australia and the Australian Capital Territory. Of these, 14,073 (87%) were working in psychology, ranging from 85% in South Australia to 90% in Victoria and the Australian Capital Territory (Table 3.22.5).
- The FTE rate of psychologists per 100,000 population for each of the above jurisdictions ranged from 54 in South Australia to 170 in the Australian Capital Territory (AIHW 2010).
- Of the registered psychologists who were not working in psychology, the majority were not actively looking for work in psychology (817).

Table 3.22.5: Labour force status of registered psychologists, by state/territory, NSW, Vic, Qld, SA and ACT, 2003

Labour force status	NSW	Vic	Qld(a)	SA	ACT	Total(b)

(b) Excludes Western Australia, Tasmania and the Northern Territory.

(c) Excludes 'whether looking for work' because this was not collected in the Queensland survey.

Source: Psychology Labour Force Survey, 2003 (AIHW 2006c).

Dental therapists

- Data from the National Dental Labour Force Collection show there were an estimated 2,075 registered dental therapists/oral health therapists in Australia in 2006.
- The proportion of dental therapists/oral health therapists employed in dentistry ranged from 58% in the Australian Capital Territory to 97% in the Northern Territory (Table 3.22.6).
- In 2009, 129 dental therapists/oral health therapists were not in paid work or not working as a dental therapist or oral health therapist.

Table 3.22.6: Practice status of dental therapists and oral health therapists, by state/territory, 2009

Labour force status	NSW	Vic	Qld	WA	SA	Tas	ACT	NT	All
Dental therapists	265	169	280	112	309	60	17	22	1,234

Percentage of dental therapists/oral health therapists employed in dentistry	84.5%	90.7%	91.5%	89.9%	83.0%	100.0%	57.6%	97.0%	87.9%

Notes

1. Not all columns/rows sum to total because weighted data have been rounded to whole numbers.
2. Oral health therapists (OHTs) are dual registered hygienist and therapist.

Source: AIHW Dental Statistics and Research Unit, 2009.

Occupational therapists

- The size of the occupational therapist labour force in Australia is difficult to estimate because occupational therapists are only required to be registered in four jurisdictions (Queensland, Western Australia, South Australia and the Northern Territory), and registration numbers were readily available from only three of these (Queensland, Western Australia and South Australia). In the 2001 ABS Census of Population and Housing, however, 5,331 persons identified as being employed as occupational therapists.
- Of the three jurisdictions where registration numbers were available, there has been an increase of 32% in the total number of occupational therapist registrations between 1998 and 2003 (AIHW 2011).
- The AIHW 2002–2003 Occupational Therapy Labour Force Survey received responses from 3,622 occupational therapists throughout Australia. Of these, 3,107 (86%) were employed in occupational therapy (Table 3.22.7).
- Of the occupational therapist respondents who were not employed in occupational therapy, the majority were not actively looking for work in occupational therapy (278). Of the occupational therapist respondents who were employed in occupational therapy, 17 were on extended leave.

Table 3.22.7: Occupational therapist respondents: labour force status and role, Australia, 2002–2003

Labour force status	Australia
Occupational therapy labour force	3,277
Employed in occupational therapy	*3,107*
Clinical occupational therapy	2,684
Non-clinical occupational therapy	423
Not working in occupational therapy	*170*

Looking for work in occupational therapy	53
Not in occupational therapy labour force	345
Overseas	67
Not looking for work in occupational therapy	278
Total respondents	**3,622**
Percentage of occupational therapists employed in occupational therapy	85.8

Note: The table excludes respondents who did not answer the labour force questions.

Source: Occupational Therapy Labour Force Survey, 2002–2003 (AIHW 2006d).

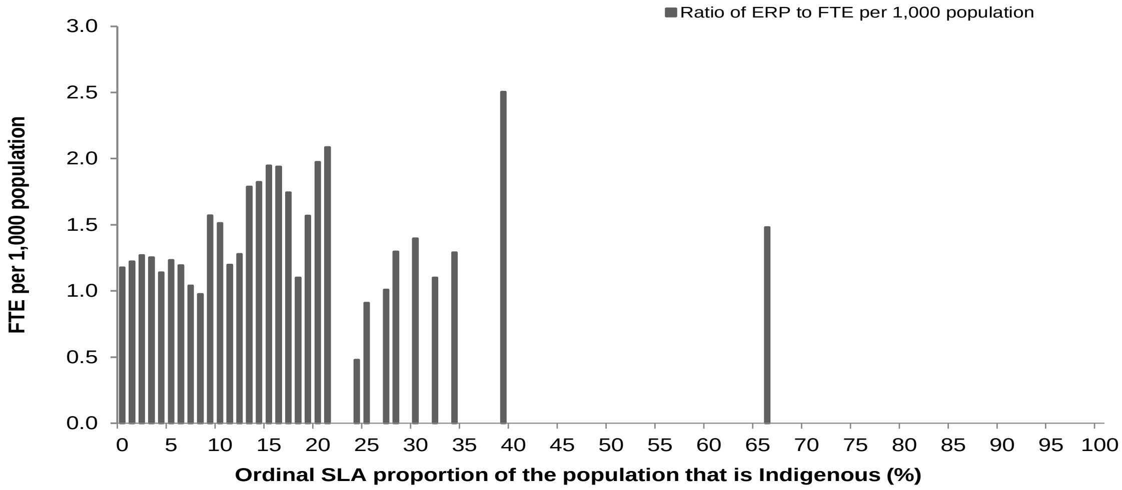
Retention

Information on the number of GPs working in Australia is available from DoHA, and additional data on GPs working in rural areas of Australia are available from the Rural Workforce Agency.

GPs by Statistical Local Area

Figure 3.22.1 presents data on the number of FTE GPs in 2010–11 per 1,000 population by the Indigenous population proportion of Statistical Local Areas ordered from low (less than 1%) to high (100%) based on the 2006 Census.

- In 2010–11, there were approximately 16,927 full-time equivalent GPs working in Australia. Approximately 58% (9,312 FTE) of GPs were working in SLAs where 1% or fewer of the population were Indigenous, and 0.2% (36 FTE) of GPs were working in areas where more than 50% or more of the population was Indigenous (Figure 3.22.1).



Note: Results for SLAs where the number of FTE GPS is less than three have been suppressed.

Source: AIHW analysis of Medicare Database.

Figure 3.22.1: Number of full-time equivalent GPs per 1,000 population, by areas of low through to high proportions of Indigenous populations, 2010–11

GPs by remoteness

Table 3.22.8 presents the number and proportion of full-time equivalent GPs by remoteness area.

- In 2010–11 as measured using the Australian Standard Geographical Classification – Remoteness Areas (ASGC-RA) system, approximately 70% of GPs were working in major cities, 28% of GPs were working in inner and outer regional areas and less than 2% of GPs were working in remote and very remote areas of Australia.

Table 3.22.8: Number and proportion of full-time equivalent GPs by remoteness categories, 2010–11

Remoteness categories (ASGC-RA)	Number of FTE GPs	Per cent
Major cities	11,917	70.4
Inner regional	3,338	19.7
Outer regional	1381	8.2
Remote	203	1.2
Very remote	88	0.5
Total	**16,927**	**100.0**

Note: As part of the Health and Ageing 2009–10 Budget Measure- Confronting the Rural Health Challenge the Government announced that from 1 July 2009, the Rural, Remote and Metropolitan Areas (RRMA) system is replaced by the Australian Standard Geographical Classification – Remoteness Areas (ASGC-RA) system. The ASGC-RA was developed by the Australian Bureau of Statistics, uses 2006 Census data, and is widely used by Commonwealth and state agencies.

Source: AIHW analysis of Department of Health and Ageing General Practice

GPs in rural areas

Table 3.22.9 presents the number and proportion of GPs working in rural areas of Australia, by length of stay in current practice and remoteness area as at 30 November 2011.

- As at 30 November 2011, the Rural Workforce Agency Annual Survey recorded a total of 6,372 GPs working in rural and remote areas of Australia. Over 1 out of 5 (22%) of GPs reported that they had stayed in their current practice for less than 12 months and 12% had stayed in their current practice for more than 20 years (Table 3.22.9).
- GPs in inner/outer regional areas were more likely to stay in current practice for a longer time than GPs in remote/very remote areas. For example, between 13% and 14% of GPs working in inner/outer regional areas had stayed in practice for 10 years or more, compared with 10% to 11% of GPs working in remote/very remote areas (Table 3.22.9; Figure 3.22.2).

Table 3.22.9: Number and proportion of GPs in rural and remoteness area, by length of stays in current practice and remoteness, 30 November 2011

Recruitment

Information on the recruitment of clinical and management staff in Aboriginal and Torres Strait Islander primary health-care services is available from the OSR data collection, collected by the AIHW, and is presented below.

Recruitment by staff category

- Over the year 2010–11, there were approximately 3,683 FTE health/clinical staff and 1,856 FTE administrative and support/management staff within Aboriginal and Torres Strait Islander primary health-care organisations funded by the Australian Government (Table 3.22.10).
- The number of reported vacancies for staff positions at Aboriginal and Torres Strait Islander primary health-care services at 30 June 2011 was 395, equivalent to 7% of all reported FTE positions (both occupied and vacant) (Table 3.22.10) . The position vacancies were higher than the previous year (295 FTE) (AIHW 2012c).
- The health related occupation categories with the highest proportion of staff vacancies were: allied health professionals (22%), other health staff (18%) and substance-use workers (16%).
- For administrative occupations, the highest proportion of vacancies were for the categories of: other admin staff (25%), cleaners/cooks/gardeners and CEO/admin/managers (each 3%) (Table 3.22.10).

Table 3.22.10: Number and proportion of health (clinical) staff and administrative and support (management) staff vacancies in Aboriginal and Torres Strait Islander primary health-care organisations, at 2010–11

Staff category	Number	Per cent[(a)]	Total occupied FTEs
Health staff			
Aboriginal health worker	74.0	7.5	916.3
Doctors	18.2	4.8	361.6
Nurses	52.6	6.2	789.1
Emotional and social wellbeing workers	33.8	6.7	467.1
Allied health professionals	49.6	22.0	176.0
Medical Specialists	0.0	0.0	13.2
Dentists / dental therapist	1.0	1.8	56.1
Dental support	1.0	1.2	79.1
Substance-use workers	28.5	15.5	154.9
Environmental health workers	0.0	0.0	37.1
Drivers/field officers	1.5	0.5	296.9
Other health staff	75.4	18.4	335.5
Total health/clinical	*335.6*	*8.4*	3,682.8
Administrative and support staff			
CEO/admin/managers	19.1	2.9	641.3
Administrative Support	7.0	1.1	605.2
Accountants	1.0	0.6	170.5
Information/data	1.5	1.6	90.9
Trainers/educators	1.0	1.9	50.8
Cleaner/cooks/gardeners	8.2	3.4	232.8
Other admin staff	21.8	25.2	64.6
Total administrative and support staff	*59.6*	*3.1*	1,856.0
Total	**395.1**	**6.7**	**5,538.7**

(a) Number of funded FTE vacancies divided by the total FTE positions (both occupied and vacant) multiplied by 100.

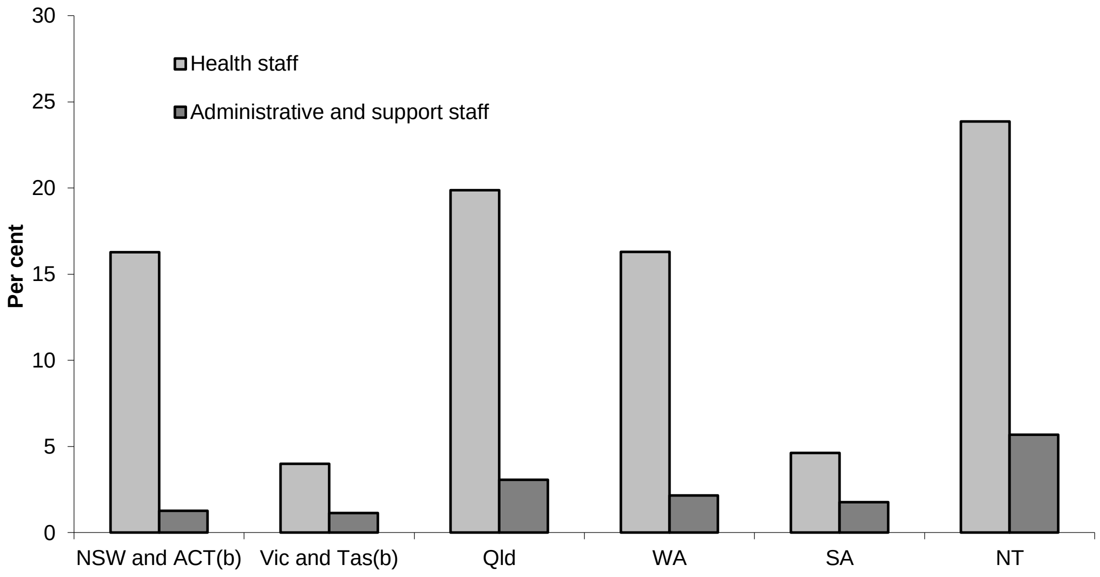
Note: One hundred and fifty-two of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data about vacant positions for 2010–11.

Source: AIHW OSR data collection.

Recruitment by state/territory and remoteness

- For the year 2010–11, the Northern Territory had the highest proportion (30 %) of total health staff vacancies (health staff, and administrative and support staff) of total FTE positions in Indigenous primary health-care organisations. Victoria and Tasmania combined had the lowest (5%) (Table 3.22.11; Figure 3.22.3). The Northern Territory had the highest number of health/clinical staff vacancies (24%) followed by New South Wales and the Australian Capital Territory combined (16%). The Northern Territory also had the highest proportion of administrative and support staff vacancies (6%).
- For the year 2010–11, outer regional and very remote areas of Australia had the highest proportion of total health staff vacancies of total positions funded in Indigenous primary health-care organisations (28% each). This compared with around 20% in remote areas,

14% in inner regional and 11% in major cities (Table 3.22.12; Figure 3.22.4). The proportion of health (clinical) staff vacancies was highest at 24% in outer regional and lowest at 9% in major cities.



(a) Number of funded FTE vacancies divided by the total vacant FTE positions multiplied by 100.

(b) Jurisdictions have been combined because of the small number of services in the Australian Capital Territory and Tasmania.

Figure 3.22.4: Proportion of health/clinical staff and support/management staff vacancies in Aboriginal and Torres Strait Islander primary health-care organisations, by remoteness, 2010–11

Recruitment by length of time vacant

- At June 2011, the majority of health and administrative positions in Aboriginal and Torres Strait Islander health-care organisations were vacant for between 4 and 25 weeks (153 health positions and 31 administrative positions) (Table 3.22.13).

Table 3.22.13: Full-time equivalent health/clinical staff and support/management staff vacancies in Aboriginal and Torres Strait Islander primary health-care organisations, by length of time vacant, at June 2011

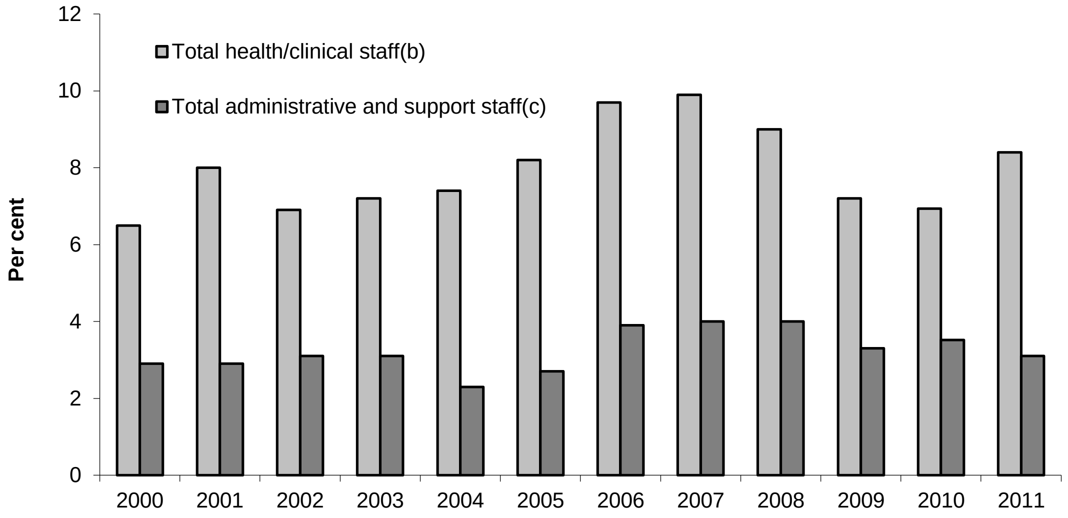
Staff category	1 week	2–3 weeks	4–25 weeks	26+ weeks	Total
Admin. and support staff	2.0	5.0	30.6	21.96	59.6
Health staff	10.8	22.8	153.45	148.51	335.56
Total	**12.8**	**27.8**	**184.05**	**170.47**	**395.12**

Note: One hundred and fifty-two of the 235 respondent Aboriginal and Torres Strait Islander primary health care services provided valid data about vacant positions for 2010–11.

Source: AIHW OSR data collection.

Time series analyses

- There has been an increase in the proportion of health/clinical staff vacancies in Aboriginal and Torres Strait Islander health-care organisations over the period 2000 to 2011 (from 6.5% to 8.4%). There has also been a slight increase in the number of administrative and support staff (from 2.9% to 3.1%) (Figure 3.22.5; Table 3.22.14).
- For the year 2011, the proportion of FTE health/clinical staff and support/management staff vacancies in Aboriginal and Torres Strait Islander primary health-care organisations was 8.4% and 3.1%, respectively.



Source: SAR and DSAR data collection.

Table 3.22.14: Full-time equivalent health/clinical and support/management staff vacancies in Aboriginal and Torres Strait Islander primary health-care organisations, year ending 2000 to 2011(a)

	Total health/clinical staff(b)	Total support/management staff(c)
2000	**6.5**	2.9
2001	8.0	2.9
2002	6.9	3.1
2003	7.2	3.1
2004	7.4	2.3
2005	8.2	2.7
2006	9.7	3.9
2007	9.9	4.0
2008	9.0	4.0
2009	7.2	3.3
2010	6.9	3.5
2011	8.4	3.1
Per cent change	**18.1**	**1.5**
Annual change(d)	**0.1**	**0.1**

(a) Number of funded FTE vacancies divided by the total FTE positions (both occupied and vacant) multiplied by 100.

(b) Represents results with statistically not significant increases or declines at the $p < 0.05$ level over the period 2001 to 2011.

(c) Represents results with statistically significant increases or declines at the $p < 0.05$ level over the period 2001 to 2011.

(d) Average annual change in number of health/clinical staff and the number of administrative and support staff determined using linear regression analysis.

Note: Since 2008–09 OSR data counts all auspice services individually when calculating rates, therefore caution should be exercised when comparing rates with earlier data collection periods.

Sources: SAR, DSR and AIHW OSR data collections.

Additional information

Factors that influence length of practice in rural and remote Australia

In 2001, a national survey of GPs practising in rural and remote communities was conducted by the Monash University School of Rural Health. The survey found that professional considerations—particularly on-call arrangements, professional support and variety of rural practice—were the most important factors determining general practice retention in rural and remote areas. Other important factors were local availability of services and geographic attractiveness. The least important factor was proximity to a city or large regional centre (Humphreys et al. 2002).

A 2004 study (Jones & Humphries 2004) reporting on the viability of rural general practice found that the key factors contributing to the viability of these practices were:

- More than half of all GPs (59%) regarded at least one aspect of practice characteristics as an important factor in contributing to viability of the practice. The most common items of practice characteristics were the characteristics of practice staff (14%), having a sufficient number of patients (11%), good practice management and efficiencies (9%) and good working relationships between partners (7%).
- Income (including Medicare rebates, hospital income, bulk-billing, and private billing practices and incentive payments). This was nominated as a key factor of practice

viability by 31% of respondents; the most frequent items here referred to private billings or realistic fees (11%), with 10% referring to adequate remuneration.

- Personal circumstances, workforce issues and community characteristics, which were each nominated by about 23% of respondents.

In terms of the factors that would put the practice at risk:

- Workforce was the most important factor considered to threaten practice viability: it was nominated by 57% of practitioners. In workforce supply items (including retention, recruitment, Overseas Trained Doctors and Temporary Resident Doctors (OTDs/TRDs)), doctor retention (21%) and recruitment difficulties (9%) were the most frequently mentioned. Workload issues included unpaid paperwork (8%) and loss of hospital work due to downgrades or closure (5%).
- Many respondents (44%) identified financial issues that threaten practice viability, with both income and expenses or costs mentioned. Inadequate Medicare rebate was cited by 16% of respondents, inadequate remuneration by 11%, and increases in practice costs by 14%.
- Medico-legal issues were raised by one-third of respondents. These issues concerned the cost of indemnity cover (18%) and concerns over the uncertainty of cover and collapse of insurers (13%).
- Fewer respondents nominated administration-political issues, community characteristics, GP/practice characteristics and personal and family circumstances (Jones & Humphries 2004).

A 2007 study reporting on retention issues for rural doctors found that doctors who were satisfied with their current medical practice intended to remain in rural practice for 40% longer than those who were not satisfied (12 years compared with 8 years) (Alexander & Fraser 2007). Those content with their life as a rural doctor intended to remain in rural practice for 51% longer than those who were discontented (12 years compared with 8 years). Continuing professional development, training opportunities, professional support and networking as well as financial support, were the doctors' top priorities. Training in Indigenous health was identified as a key information deficit by most doctors.

Data quality issues

National Health Workforce Data Set (NHWDS)

The Australian Health Practitioner Regulation Agency (AHPRA), in conjunction with the national boards, is responsible for the national registration process for 14 health professions. The data from this annual registration process, together with data from a workforce survey that is voluntarily completed at the time of registration, forms the National Health Workforce Dataset (NHWDS). Data in the NHWDS includes demographic and employment information (for example labour force status, location of main job, area of practice, work setting) for registered health professionals

Medical practitioners

The NHWDS: medical practitioners contains information sourced from registration data and workforce survey data.

The 2010 data collection is the first data release from the new national registration scheme. The data set is comprised of registration (including demographic) information provided by the Australian Health Practitioner Regulation Agency (AHPRA) and workforce details obtained by the Medical Workforce Survey. The survey instrument varies significantly in some areas from previous years, however, is now nationally consistent.

The 2010 collection excludes the workforce survey records of medical practitioners whose principal state of practice was Queensland and Western Australia, because not all registrations in Queensland and Western Australia expired on 30 September 2010, the date prescribed by AHPRA as the official closing data for registration renewal.

Estimates published from the Medical Workforce Survey 2010 are not directly comparable with estimates derived from the earlier AIHW Medical Labour Force Survey data. This is due to a change in the data collection methodology; including the survey design and questionnaire. For further information, refer to the Data Quality Statement and the online *User guide for the NHWDS: medical practitioners 2010,* available from the AIHW website.

DoHA general practice statistics

Care must be taken in using and interpreting the data provided. There are two issues to note which have an effect on the quality of the data. First, the data include only those services claimed through the Medicare system. Consequently the full-time equivalent for doctors in remote areas, which are more likely to have high proportions of Indigenous population, will be understated. This is because some services are provided in rural hospitals and through the Royal Flying Doctor Service. There is also anecdotal information that services provided in Aboriginal Medical Services are often not claimed through the Medicare system. This results in further understating the full-time equivalent for doctors in areas with high Indigenous populations.

Second, the data at the grouped SLA level can hide variability in data at the individual SLA level. For example, although one group of SLAs may have fewer people per doctor overall than a second group of SLAs, there will be a number of individual SLAs in the first group with far more people per doctor than in some individual SLAs in the second group.

OATSIH Service Reporting (OSR) data collection

The data were collected using the OSR questionnaire, which combined previously separate questionnaires for primary health, stand-alone substance use, and Bringing Them Home and Link Up counselling services.

AIHW sent a paper copy of the 2010–11 questionnaire to each service and requested completion of relevant sections. The AIHW examined all completed questionnaires and identified three major issues with the data quality: missing data, inappropriate data provided for a question, and lack of coherence of data from two or more questions. The majority of questionnaires received had one or more of these data quality issues. Where needed, AIHW staff contacted services to follow-up and obtain additional or corrected data. After entering the data on the data repository system, staff conducted further data quality checks. It should be noted that some data presented in this report—particularly around client numbers, episodes of care and client contacts, are estimates of actual figures and should be used and interpreted with caution.

Further information can be found in the data quality statement in the *Aboriginal and Torres Strait Islander Health Services Report, 2010–11* (AIHW 2012c).

Rural Workforce Agency National Minimum Data Set

The Rural Workforce Agency National Minimum Data Set is a national data set based on annual surveys conducted by each state and territory Rural Workforce Agency and compiled through the Australian Rural and Remote Workforce Agencies Group (Health Workforce Queensland and New South Wales Rural Doctors Network 2009). The data are collected in accordance with an agreed national minimum data set and data dictionary.

WHO	World Health Organisation

This report provides the latest information on how Aboriginal and Torres Strait Islander people are faring according to a range of indicators on health status, determinants of health and health system performance that are based on the Aboriginal and Torres Strait Islander Health Performance Framework. It highlights the main areas of improvement and continuing concern. For example, while death rates for avoidable causes and circulatory diseases have declined since 1997, more than half of Aboriginal and Torres Strait Islander mothers smoke during pregnancy and about one-quarter of Indigenous Australians aged 15 and over live in overcrowded housing.
